The China Indemnity.

ALTHOUGH the situation in China is now such that the present would scarcely seem an opportune occasion for the discussion of methods of educational development, a note of optimism and reassurance is not absent from the Report of the Advisory Committee established under the China Indemnity (Application) Act 1925, which was presented to Parliament last week.[1] This Committee, it will be remembered, was constituted to advise the Secretary of State for Foreign Affairs on the methods of applying the so-called Boxer Indemnity to purposes "beneficial to the mutual interests of His Majesty and of the Republic of China." When the Committee took up its duties at the beginning of 1926, it decided to send a delegation of six of its own members—three English and three Chinese—to investigate conditions on the spot. The report of this delegation occupies four-fifths of the report of the Committee.

The report of the delegation is in many respects an illuminating document. While it does not, indeed, deal with matters not strictly germane to the inquiry, it serves to throw light on many of the political, social, and economic difficulties of the moment. Although it bears witness to the courtesy and assistance the delegation received at the hands of the Chinese, official and other, not the least of the difficulties encountered arose from the suspicion prevalent among the Chinese that the motives of Great Britain were not disinterested. This attitude was undoubtedly due to a misunderstanding, and the delegation thought it expedient to publish an explanatory memorandum with the object of removing it. So strong, however, was the impression made on the members that they recommend that the future management of the fund should be in the hands of a board of trustees established in China, who will supersede the advisory committee. In this way, it is considered, it will be possible best to fulfil the desire to administer the fund according to Chinese ideas. The board will consist of eleven members, of whom six will be British and five Chinese. After 1945, British members may be replaced by Chinese as vacancies occur.

Before the delegation left England, a memorandum had been drawn up by the chairman of the Committee, Lord Buxton, for the guidance of the members. This had received the approval of the Chinese members. In this memorandum it was assumed that the purposes for which the indemnity was to be used were entirely educational. There was, however, a reference to the fact that an influential body of opinion had urged that a considerable portion of the fund should be used for railways, or public works. The members of the delegation themselves were, indeed, much impressed by what they saw of the importance of agriculture and the peasant in the social and economic conditions of China, as well as by the need for improved methods of cultivation.

---

[1] Report of the Advisory Committee, together with other Documents respecting the China Indemnity. (London: H.M. Stationery Office, 1926) Price 3s. 6d. net.

It is essential that these facts should be kept in mind in judging the weight of the considerations which have guided the delegation in framing its recommendations. It must be remembered that while education was the primary consideration, the needs of China as a whole, and not a section of it, as well as the desires of the Chinese themselves, had to be taken into consideration. The delegation wisely decided that provision should be made for carrying on the work now to be initiated after 1945 when the annual payments come to an end. The total fund, amounting to about 11,000,000*l.*, accruing between 1922 and 1945, is to be divided into two parts: (*a*) an annual sum of about 350,000*l.* (out of an annual average amount of about 500,000*l.*) for immediate expenditure, and (*b*) capital for the formation of an investment fund, for which provision is to be made by raising a sum not less than 3,500,000*l.* and not exceeding 5,200,000*l.* for permanent investment. It is suggested that this be applied for some useful national reproductive undertaking, such as railways or river conservation, or if they do not provide adequate security, gilt-edge securities. This first course would ensure the desire of the Chinese that advantage should accrue from the fund to objects of national importance other than education. On the amortisation of the indemnity fund, the proceeds from the investment fund are to be applied to the continuation of the educational and other work. These proposals are endorsed by the Committee so far as the twofold allocation of the indemnity fund is concerned; but caution is recommended in dealing with the investment fund. It is calculated that the latter will produce rather more than five millions.

Turning to the proposals for immediate expenditure, it is recommended that the annual sum be applied in the following proportions:

Agricultural Education and Improvement (including 5 per cent. for famine relief and rural credit) .	30 per cent.
Scientific Research . . .	23 per cent.
Medicine and Public Health . . .	17 per cent.
Other Educational Purposes . .	30 per cent.

While a number of interesting suggestions are made under each of these heads, they are in no way mandatory, and considerable discretion is to be left to the trustees in allocating the fund. These suggestions, when examined in the light of the detailed information given in the body of the report, can only be regarded as the outcome of a very clear view of the needs and possibilities of the situation. In agriculture, for example, agricultural colleges are to be established, scientific study of the culture of the silk-worm is suggested, and an Institute of Rural Economics is proposed. Under the heading of scientific research is suggested the establishment of a National Research Institute. It is generally acknowledged that provision for research is one of the greatest needs of China in higher education, and it may be noted that provision for research is also suggested as one of the objects of the subsidy for university education.

In considering the claims of what is here called "direct educational purposes," the delegation had before it a serious problem in relation to elementary education. The funds at the disposal of the trustees will be far too small to admit of any subsidy on a large scale. Further, it was felt that it was not expedient that they should assist elementary education, which is a national duty. Secondary education, however, and particularly secondary education for girls, is recognised as of importance and is to be encouraged so far as possible in the matter of staff and equipment. In university education, the provision of professorships, equipment for library, laboratory, and research are among the objects mentioned. It is interesting to note that an endowment for a chair in Chinese at the School of Oriental Studies, London, and similar provision at Oxford, Cambridge, and elsewhere, are recommended.

Some stress has been laid from time to time on the advantage in increased understanding which would accrue from the education of selected students in England. This, however, the delegation does not recommend, at least on any large scale, and the experience of the Japanese and American schemes leaves little room for doubt that this decision is sound.

Taken as a whole, the report is a document which summarises the present educational situation in China with a remarkably clear view of essentials. The work has been well done. The claims of the more urgent needs of the country have been carefully weighed and the various interests nicely adjusted. Some disappointment may be felt by those who hold that so small a sum relatively might have been better employed in an existing or new institution of university rank. Possibly, however, its wider dispersion through more numerous channels may serve the greater good in the long run by stimulating public effort in a larger number of directions when China once more becomes an organised State.

The Training of a Sociologist.

My Apprenticeship. By Beatrice Webb. Pp. xiv + 459 + 12 plates. (London: Longmans, Green and Co., Ltd., 1926.) 21*s*. net.

AMONG the various kinds of people in the world, certainly the most interesting are those who have tried to understand the meaning and purpose of human life, and express their conclusions in word and deed. It is rather astonishing to reflect how few these are, and how diverse their results. The complexities of human behaviour are such that most investigators appear to belong in some measure to the kingdom of the blind, finding only the tail or trunk of their elephant instead of the whole beast. Mrs Webb is not without limitations, but the extent of her knowledge and the breadth of her comprehension place her among the foremost living sociologists, the more to be admired on account of the practical results of her activities. Becoming a sociologist, she also became a socialist, but of a plastic opportunist type rather than a rigid Marxian.

How all this happened to a young woman of good social standing, intended to grace the halls of conventional society, is told at length in "My Apprenticeship." In the very dawn of life and during the years of development Herbert Spencer was a significant factor. When only twenty-four, Spencer had made the acquaintance of Mr. and Mrs. Potter—Mrs. Webb's parents. They made an extraordinary impression on him, and he recorded that they appeared to him the most admirable pair he had ever seen. Spencer said of Mr. Potter: "He is, I think, the most lovable being I have yet seen. . . . I must say I felt so strongly the beauty of his disposition as contrasted with my own, that I felt more dissatisfied with myself than I have done for a long time past." The friendship thus begun lasted as long as life, and Spencer was "the philosopher on the hearth" at the Potters', in spite of the fact that Mr. Potter never could interest himself in the synthetic philosophy. When Spencer died, it was Beatrice Potter, already married to Sidney Webb, and holding opinions strongly opposed to those of the philosopher, who ministered to his broken spirit. She records in her diary of December 1903: "My old friend passed away peacefully this morning. . . . 'My oldest and dearest friend,' he has called me these last visits. 'Let us break bread together,' he said on Monday, and insisted on a plate of grapes being set on the bed and both of us eating them. 'You and I have had the same ends,' he repeated again; 'it is only in methods we have differed.'"

The contact with Spencer, and with other intellectual men who came to the house, could not fail to have potent influence. The diary of 1881 records: "Mr. Spencer's visits always interest me and leave me with new ideas and the clearing up of old ones." Growing up in such circumstances, endowed with a keen mind and a warm heart, it is not surprising that Beatrice Potter came to question the accepted views of conventional society and orthodox religion, and was much perplexed about her duty and conduct. In this state of mind she might have been converted to some religious or political faith, and have gone through life a fanatical advocate of a particular brand of salvation. Instead of this, she sought relief in contact with realities, in experiences which might reveal to her the hidden meaning of the maladjustments which she could clearly perceive.

That Miss Potter took the scientific rather than the emotional path may well have been due to her early scientific contacts; but the revelation of the workings of her adolescent mind, given with the utmost frankness, should interest any psychologist. There were certain notable limitations; thus she says: "Owing to a mental defect, which I believe is not so uncommon as it is unrecognised and unrecorded, the whole realm of poetry was closed to me: I was poetry blind, as some persons are colour blind." Yet she was not at all devoid of feeling; indeed her diaries indicate rather an excess of sensitiveness with regard to her own personality and affairs. The abandonment of orthodox religion left her with "not even an affirmation by the intellect of the existence of a spiritual power with whom man could enter into communion, but an intuitive use of prayer as, for one of my temperament, essential to the right conduct of life . . . by prayer, by communion with an all-pervading spiritual force, the soul of man discovers the purpose or goal of human endeavour, as distinguished from the means or process by which human beings may attain their ends."

Gravitating toward the field of practical sociology, Miss Potter in 1883 conceived the plan of what she now calls "a sentimental journey." Her mother's family, the Heyworths, had come from among the working classes of Lancashire and Yorkshire. The old nurse, affectionately called 'Da,' used to visit at Bacup, where some of the variously remote cousins still lived and belonged to the 'working classes.' Why not go to visit them? But, said the nurse, they are not accustomed to such grand folk. "'Oh,' cried I, jumping up with the delightful consciousness of an original idea, 'I wouldn't be Miss Potter, I would be Miss Jones, farmer's daughter, near Monmouth.'" It was so arranged, though it was difficult to break the nurse of the habit of calling her 'm'am.'

The visit was very successful, and was repeated in following years. Miss Potter was attracted by the earnest simplicity of the people. She says:

> "In living amongst mill-hands of East Lancashire, I was impressed with the depth and realism of their religious faith. It seemed to absorb the entire nature, to claim as its own all the energy unused in the actual struggle for existence. Once the simple animal instincts were satisfied, the surplus power, whether physical, intellectual, or moral, was devoted to religion. Even the social intercourse was based on religious sympathy and common religious efforts. It was just this one-idea'd-ness and 'transparentness of life which attracted my interest and admiration. For a time it contrasted favourably with the extraordinarily complex mental activity arising in the cosmopolitan life of London—an activity which in some natures tends to paralyse action and dissipate thought."

The great opportunity and experience came to her when Charles Booth, at his own expense, undertook his investigation of the conditions of life and labour of the London people. This extended over seventeen years, and the results were published in a series of volumes which have ever since been recognised as of classic importance. Through participating in this inquiry, Miss Potter came to understand the practical problems of urban life in all its details, and also to appreciate the importance of intensive work in this field. The opinions she formed, like those developed by Booth himself, were gradually matured in the presence of an ever-increasing mastery of the facts. Charles Booth was a wealthy captain of industry, "conservative in politics and strongly anti-socialist in temper and economic views," yet he emerged from his long study with "proposals the very reverse of individualist." He conceived that it was the duty of the State to take over the control of the lives of the very poor, under a socialistic type of administration, while leaving the more capable section of society to its own devices, with individualism dominant.

Beatrice Potter had now become a well-known social investigator, and thought of this work as her chosen calling. She studied the 'sweating' problem, deciding that the real sweater is not some malevolent Jew, but the nation itself. She took up the history and results of the co-operative movement, and in the course of these studies found herself in need of certain information. "'Sidney Webb, one of the Fabian essayists, is your man,' casually remarked a friendly woman journalist. 'He knows everything; when you go out for a walk with him he literally pours out information.'" In February 1890, the diary records: "Sidney Webb, the socialist, dined here to meet the Booths. A remarkable little man with a huge head and a tiny body, a breadth of forehead quite sufficient to account for the encyclopædic character of his knowledge. A Jewish nose, prominent eyes and mouth, black hair, somewhat unkempt, spectacles, and a most bourgeois black coat shiny with wear. But I like the man. There is a directness of speech, an open-mindedness, an imaginative warm-heartedness which will carry him far."

So it came about that the apprenticeship of Beatrice Potter came to an end, and her long and happy partnership with 'the other one' began. Concerning that we may hope to hear full particulars at some later date.

T. D. A. COCKERELL.

The Diphtheria Bacillus and Related Organisms.

Annals of the Pickett-Thomson Research Laboratory. Vol. 2, No. 2, July 1926. Pp. iv+29-203+50 plates. (London: Baillière, Tindall and Cox; Baltimore, Md.: Williams and Wilkins Co., 1926.) 42*s*. net.

THIS volume is almost entirely devoted to a study of Corynebacteria (diphtheria bacillus and 'diphtheroids'), with special reference to the importance of microphotography as an aid to their classification and identification. The writers are the Director and Pathologist of the Pickett-Thomson Research Laboratory, Drs. David Thomson and Robert Thomson.

The greater part of the letterpress is given up to a comprehensive review of the literature of the genus. Much of this of necessity covers ground very adequately dealt with in the monograph on diphtheria published by the Medical Research Council (1923), to which acknowledgment is made. A feature of the present survey which will be found very useful for reference is an alphabetically arranged list of probably all the named diphtheroids to be found in the literature, together with a short account of each and the authors' comments on the records. Chapters are also devoted to the distribution of the genus, to the pathogenicity, and to previous attempts at classification. The latter show the great complexity of the subject, the confusion resulting from the unavoidable inadequacy of the earlier attempts, and the difficulties still encountered in the present state of bacteriological knowledge.

In the system of classification advocated in this memoir, the importance of photographic records of the organism in both microscopic preparations and cultures is emphasised, though other cultural and biochemical characters are detailed. Seventy-two varieties of diphtheroids are described, with plates of each, but the total number of strains examined is not stated, and in some of the varieties the fermentation reactions are not recorded.

The routine recommended by the authors in examining a diphtheroid is as follows: The macro- and microscopic characters of the growth are observed on standard solid and liquid media. These cultures and stained microscopic preparations are compared with photographs of diphtheroids previously examined If the organism under investigation does not correspond with any of the existing records, it is itself photographed and added to the collection. Afterwards the fermentation reactions are examined, and in most cases the pathogenicity of the strain for the guinea-pig is tested.

From the character of the growth on testicular agar a preliminary division into five groups is made:

Group I. Non-chromogenic, profuse growers, aerobic or facultative (22 varieties).

Group II. Non-chromogenic, profuse growers, anaerobic (4 varieties).

Group III. Non-chromogenic, delicate growers, aerobic or facultative (25 varieties).

Group IV. Non-chromogenic, delicate growers, anaerobic (5 varieties).

Group V. Chromogenic, profuse growers, aerobic or facultative (16 varieties).

The variety is determined by ancillary cultural characters and morphology. The fermentation reactions give the type.

The authors agree with the writers of the diphtheria monograph in deprecating the naming of individual members of the genus and suggest that individual strains be designated by a Roman numeral indicating the group, a fermentation formula showing the type, and a number giving the variety.

Whilst a study of the authors' plates and accompanying descriptions shows that much time and labour have been expended on the work, the mass of detail is so great that the general impression given is one of great complexity. Indeed, the authors themselves at times seem to have some difficulty in deciding the position of a strain. They appear to desire to emphasise the great variety of diphtheroids encountered in routine examinations. Few, if any, modern bacteriologists will dispute this point, but what those who have had most experience of the genus will feel is that, owing to the variations, especially in morphology, to which the genus is liable, any method of identification in which morphology and minor cultural characters play an important part must hold the possibility, nay, the certainty, of many errors, especially if, as the authors seem to contemplate, the organism is 'placed' on the evidence of a single examination.

It is claimed by the authors that this difficulty can be overcome by the use of a satisfactory medium, but this we are inclined to doubt. Whilst the more obvious cultural characters, such as thickness or thinness of growth, on which the authors base their primary grouping, will, as a rule, remain constant on any given medium properly prepared, variation in the finer points may occur even on the same batch of medium, and morphology is notoriously variable A sentence in the Medical Research Council's monograph would seem to be conclusive on the latter point. "When different portions of the same serum slope are examined, very great differences may be detected in the proportion of the different (morphological) types" The reference is to the diphtheria bacillus and not to diphtheroids, but though it is true that in many diphtheroids the number of morphological types present is smaller than in *C. diphtheriæ*, in others considerable pleomorphism exists. Indeed, many such are shown in the authors' plates.

The book is well printed and the great majority of the photographs well reproduced. The latter, with the accompanying notes, are of considerable value in demonstrating the great variety of morphological and cultural characters to be found among Corynebacteria.

The volume also contains a further note by Dr. David Thomson on the pleomorphic Gram-negative bacillus associated with measles, and a paper on the etiology of tuberculosis in relation to satisfactory immunisation in cattle by Dr. J. J. Thomson.

M. M B.

British Late Palæolithic Industries.

The Upper Palæolithic Age in Britain. By D. A. E. Garrod. Pp. 211+3 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1926.) 10*s*. 6*d*. net.

THIS book indeed fills a gap. Not since 1897, when the second edition of Evans's "Ancient Stone Implements . . ." appeared, has there been any attempt to study systematically the palæolithic history of Britain. The present volume only deals with a small portion of the story, but it is to be hoped that the author will not stop short and that further work on the other periods will appear later to complete the picture.

Miss Garrod has learnt her subject in France under the Abbé Breuil and others, and her terminology and indeed her whole thought is French. The reader who is not familiar with the French classifications may find himself now and then at sea, but clearly the present volume is intended rather as a book of reference for the student of the subject than as arm-chair reading for the casual inquirer. As such it amply fulfils its purpose. There are numerous illustrations.

Britain is divided into geographical areas, each of which is dealt with in a chapter, but Miss Garrod is careful to point out that this method is only employed for convenience' sake and that no idea that each area shows a different culture is implied.

After a charming little preface in French by Breuil and a short introduction, Devonshire finds are discussed, and, as will be expected, Kent's Cavern is given a foremost place and occupies the lion's share of the chapter. This is the first time that the most important British cave site has ever been systematically described. Except for a note on Bench Cavern, Brixham, other palæolithic finds of the county are omitted. Neither the Tor Bryan Caves situated near Denbury, nor the Happaway Cave, Torquay, nor the cave at Cattedown near Plymouth, where human remains were found, appear, though they are all mentioned by Evans. Would it not have been well at least to have catalogued them, even if unimportant?

The next area discussed is South Wales. Here comes an excellent condensed account of Paviland. Some notes on several other small caves in the district follow. A few pages (with figure) on King Arthur's Cave in the Wye Valley form the third chapter, but as this district is at present being investigated by the Spelæological Society of the University of Bristol, it is probable that a second edition will show a considerable amplification here.

An account of the Mendip region follows, including Aveline's Hole, Gough's Cave, Wookey Hole, Hyena Den, etc. Although the first of these has been published by the Spelæological Society of the University of Bristol in its *Proceedings*, it has not attracted hitherto all the attention it deserves.

The North Welsh caves are next passed under review, and this chapter is all too short; the district calls for further investigation in the field.

After a note on the Victoria Cave, Settle, Yorkshire, the Derbyshire caves are described. Creswell Crags take naturally chief place. Mr. L. Armstrong's recent and still unfinished work there has revolutionised our ideas on the industries found. To a certain extent, therefore, Miss Garrod's account is necessarily an epitome of that published in the *Journal of the Royal Anthropological Institute* for January 1925, but none the less, here as elsewhere, she has carefully studied the finds in person.

The book concludes with a second part containing notes on a few open-air finds that are possibly Palæolithic in culture, followed by a short sketch on some transitional industries, and finally a general summary and conclusions, bibliography, etc.

The treatment of the earlier part of this section is perhaps too slight. Surely any account of the open-air sites in eastern England should form part of a much larger discussion on the whole problem of the surface finds of East Anglia, some of which may be quite possibly Upper Palæolithic in age. Lastly, may one dissent from the use of the term 'Creswellian' for those late Palæolithic cultures occurring on the edge of the Magdalenian world, which, though derived from the same basal Neanthropic stock, did not actually develop into the Magdalenian culture. Late developments of the Aurignacian culture are found all round the periphery of the Magdalenian world, and show more or less influence from the splendid Magdalenian culture of France. There is a danger that the name of a species would be given to the genus and that the term 'Creswellian culture' would become on a par with the term 'Cromagnon race'—that unfortunate use of the name of a site where one modification of the Neanthropic race was found, for the race itself.

One can only conclude by hearty congratulations to Miss Garrod. Her book is the first systematic account of the Upper Palæolithic cave cultures in Britain that has appeared in the light of modern knowledge, and she may justly be proud of the result.

M. C. Burkitt.

Vinegar.

Vinegar: its Manufacture and Examination. By C. Ainsworth Mitchell. Second edition, thoroughly revised. Pp. xvi+211+5 plates. (London: Charles Griffin and Co., Ltd., 1926.) 10*s.* 6*d.* net.

VINEGAR or 'Alegar,' as the body when derived from beer was originally called, has been in household use from early times; it has been the subject of organised manufacture for generations; and for 250 years in Great Britain was an object of taxation for revenue purposes—a policy which still exists in some other countries. There is therefore a wealth of interesting historical material from which Mr. Mitchell has been able to draw in this manual on vinegar.

The early story of vinegar and its manufacture, the legislation affecting it, the theories advanced to account for acetic fermentation, as well as illustrations of the apparatus in use a century ago, some of it surviving in a few cases to-day, form a considerable part of the book. But modern processes of manufacture have not been overlooked, and on this portion the author speaks with the authority of an experienced worker.

The manufacturing details and the treatment of the crude vinegar show how the factors used by chemists a quarter of a century ago for determining the purity of a vinegar, as well as the definition of what is understood by vinegar, need revision. An effort has, indeed, recently been made in a Bill before Parliament to lay down a definition of vinegar, but the author does not refer to this although he gives the proposals on the same point put forward by the Vinegar Brewers' Association in 1908.

The methods for the examination of vinegar are on the whole fairly complete, although reference has to be made to the appendix for some of these. A full description of the method for the determination of arsenic by the Marsh zinc and acid method described in a report to the Royal Arsenical Commission in 1901, is included, but it would have been as well to record that the Commission had also before it the electrolytic method which is now very largely used.

It is unfortunate that the appendix has been used to describe several pieces of modern work, instead of their inclusion in the text in this 'revised' edition. Thus, in reading the account of the manufacture of acetic acid in Chap. v., there is a sense of loss that no reference is made to the synthesis from acetylene. This, however, is given in the appendix, together with other matters such as the modern classification of acetic bacteria suggested by the American Society of Bacteriologists in 1920. The book would have been more clearly up-to-date if these had been included in their relevant places in the text.

The appendix also gives a list of the import duties of different countries on vinegar and acetic acid, presumably as a guide to intending exporters. It would have been of advantage to give also the definitions for the various types of vinegar which have been adopted by some of these countries with which imported vinegar must conform.

The book is, however, a very useful addition to technical literature.

Our Bookshelf.

Zoologie im Grundriss. Von W. Stempell. Dritte Lieferung. Pp. 337-512. 6·90 gold marks. Vierte Lieferung. Pp. 513-688. 6·90 gold marks. Funfte Lieferung (Schluss des Werkes). Pp. xx + 689-900. 10·50 gold marks. (Berlin: Gebrüder Borntraeger, 1926.)

THE early portion of the third part of this text-book contains the remainder of the general account of the structure of the Vertebrata. The few pages on development might have been extended with advantage, and the systematic accounts of the classes of vertebrates also suffer from undue compression—the elasmobranchs are dealt with in 40 lines, the Dipnoi in 20 lines, and the Rhynchocephalia in 10 lines.

The succeeding section is devoted to physiology and development. A brief account of the principal inorganic and organic substances met with in animals is followed by a consideration of the various aspects of metabolism, and (continuing into the fourth part) excretion, with short accounts of pigments and animal coloration. The transformation of food into energy and the production of electricity and light are considered, and an account is given of the sense organs—especially eyes and statocysts, which are concerned in directing movement, and of the general relationships of the neurones in the central nervous system concerned in reflexes. The last section of the part deals with reproduction and development and here again the difficulties due to compression are apparent.

The fifth part opens with a brief account of heredity, followed by a section on the relation of animals to their environment and on evolution, concluding with a short chapter (9 pp.) on the descent of man. A list of books and of journals is given for the use of those who wish to pursue their studies further.

A concise summary is provided so that the student can review, by reading some fifteen pages, many of the important matters which have been dealt with in the volume.

The diagrammatic figures are for the most part good and helpful, but some of the others scarcely fulfil their functions, *e.g.* the figure of Archæopteryx would have been of much more use to the reader had its parts been lettered. At the end of the volume are one hundred reproductions of photographs made chiefly by the author, and there is an excellent index.

The book as a whole is very condensed, but the student who works through it and grasps the facts and principles set forth, if he is at the same time developing his knowledge of comparative anatomy, embryology, and microscopical structure by sound work in the laboratory, will have received an all-round introduction to the study of animal life.

Business Economics. By Sir William Ashley. Pp viii + 71. (London: Longmans, Green and Co., Ltd., 1926.) 2*s.* 6*d.* net.

NOTWITHSTANDING the growing attention which is being paid to-day to the importance of the study of economics, there is as yet no real assurance that its teachings are having any deep effect upon the minds of the great mass of business men. It may be that it is yet too early to look for this result. While economics is slowly winning its rightful place in the syllabuses of many professional examinations, it is doubtful whether either the younger or the older practical business man ever has its claims brought before him in a manner which both attracts and ensures his attention. If this end is to be achieved, it can only be through the influence of books specially written with this purpose in view, and it is within this sphere that Sir William Ashley's little book on "Business Economics" has a particular claim. It consists of a reprint of three lectures delivered by him this year at the Commercial College at Copenhagen. Its main purport is to emphasise the importance of overhead charges or expenses in the determination of business policy.

Much of the dislike and the distrust that a practical man of affairs shows towards economics spring from the difficulty he has of finding within the written page any immediate help towards the solution of the practical problems with which from time to time he is faced. Such a man seeks a definite answer to a definite question, and all he can find in the text-book is a broad answer to a broad question. His interest in economic literature is therefore never likely to develop until some practical link is established between general theories on one hand and particular problems on the other. By analysing the influence of overhead costs, Sir William Ashley makes an important contribution towards forging this essential link. He shows how and why 'dumping' arises. He considers its reaction on the wage policy. He discusses the advantages and disadvantages of integration and vertical combinations, and also of the policy of broadening the basis of business. The relation of dividends to profits, with the corollary of reserves, also receives attention, and a few words are devoted to the question of publicity.

The field of business economics calls, as Sir William Ashley notes in his concluding lines, for much further investigation, and we venture to hope that he will pursue his studies and so develop this side of knowledge that it will, in his own words, "contribute to the training of efficient men of business . . . form in itself an interesting body of knowledge and . . . be a genuine mental discipline."

W. H. C.

Handbuch der Pflanzenanatomie. Herausgegeben von Prof. K. Linsbauer. Lief. 15. Abteilung 2, Teil 2: Pteridophyten und Anthophyten. Band 9: Das abnorme Dickenwachstum. Von Dr. H. Pfeiffer. Pp. xii+273. 19·50 gold marks. Lief. 14. Abteilung 2, Teil 2: Pteridophyten und Anthophyten. Band 10: Anatomie der Angiospermen-Samen. Von Prof. Dr. Fritz Netolitzky. Pp. v+364. 27 gold marks. (Berlin: Gebrüder Borntraeger, 1926.)

THESE two volumes, forming part of a comprehensive series dealing with all aspects of plant anatomy, contain a wealth of detail useful to the specialist and, expecially in the case of Pfeiffer's book, not without considerable interest to the general botanist. Pfeiffer deals essentially with the various types of anomalous secondary thickening found in lianes and perennial storage organs, the detailed consideration of which, arranged under numerous headings, occupies the greater part of the book. The introductory section includes a brief summary of the present views as to the causal interpretation of the phenomena concerned and a useful oversight in tabular form of the occurrence of the different types of anomalies in the various Phanerogamous families. The treatment of a large mass of (in part) rather unconnected facts has been successfully accomplished, but a rather fuller consideration of fleshy roots might have been useful. The illustrations are somewhat scanty—in particular figures showing successive stages in development of anomalous structure might have been more freely included.

Netolitzky's treatise on the anatomy of Angiospermous seeds, which traverses a very large body of literature, deals with the subject-matter essentially from the systematic point of view. Seed structure is considered family by family and the data are summarised in a table at the end of the book. One misses, however, anything of the nature of a synopsis giving the distribution of the various seed characters in families and genera, such as would facilitate identification of a seed of unknown affinity. The numerous illustrations may help to some extent to remedy this defect.

Le pH intérieur cellulaire. Par Dr. Paul Reiss. Pp. 135. (Paris: Les Presses universitaires de France, n.d.) n.p.

THIS monograph provides an excellent summary of the literature in a field of experimental biology which is beginning to attract great attention. After a very summary statement of the theoretical physico-chemical basis from which conclusions may be drawn as to the significance of hydrogen ion concentration to the behaviour of protoplasm, a brief chronological summary is given of the main investigations in which an attempt has been made to determine a *p*H of biological interest. As the author says, when placed chronologically, these investigations do not show a growing improvement in the technique of determination of *p*H, the difficulties grappled with in earlier papers often being completely neglected by later workers.

The intention of the author is to avoid this in future by a comprehensive study of the literature of *p*H determinations of significance in biology, and a very valuable section follows in which a critical discussion is given of the use and limitations of both indicator and potentiometric methods when applied to living organisms. A brief but very suggestive discussion of the tentative suggestions as to the significance of *p*H, for example, as an internal regulatory mechanism in the organism, completes a very concise monograph that should be of real value to the experimental biologist.

The bibliography covers English and American work as well as continental, and cites a number of papers published so late as 1926. It is an additional advantage that this little monograph discusses somewhat fully the suggestive work of Prof. Vlès and his pupils, both in the development of methods of determination of *p*H and as to the significance of external *p*H on the behaviour of mixtures of protein ampholytes with different iso-electric points.

Die Tierwelt der Nord- und Ostsee. Herausgegeben von G. Grimpe und E. Wagler. Lieferung 4. Teil 7, c_1: *Bryozoa*, von Ernst Marcus; Teil 12, c.: *Pisces, Allgemeiner Teil*, von H.M. Kyle und E. Ehrenbaum; Teil 12, g_1: *Teleostei Physoclisti*, 1-5, von Georg Duncker und Erna W. Mohr. Pp. 100+104+44. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1926.) 18 gold marks.

THE present part of the "Tierwelt der Nord und Ostsee" maintains the useful character of the preceding numbers, the section by Marcus on the Bryozoa being particularly well done, comprehensive, and embodying all recent work. It receives treatment on the lines already laid down, which are to be followed throughout the whole work in dealing with each group. The full account of the habitats of the species, and a detailed key, together with figures elucidating the morphology of a large number of species, will be very valuable to zoological workers.

The general introduction to fishes given here by Kyle and Ehrenbaum comprises a rapid survey of their systematics, morphology, and biology; though necessarily brief, it is good. Systematists will find Kyle's views on classification and the phylogenetic scheme which places the Cyclostomata amongst the Chondrichtyes on a level with the elasmobranchs provocative and stimulating. Of greater service to the naturalist are the artificial keys to the families and to the eggs of North Sea species so far as they are known. Detailed descriptions of the families, species, and of their life histories are to be given in the systematic portions as they appear; the scombresociformes, syngnathiformes, Plectognathi, atheriniformes, and ammodytiformes occurring in the present volume.

Letters to the Editor.

The Supposed Law of Flame Speeds.

AT the general discussion upon explosive reactions in gaseous media, held in London on June 14 under the auspices of the Faraday Society, Prof. R. V. Wheeler and Dr. W. Payman presented a paper on the uniform movement during the propagation of flame, in which they emphasised their supposed 'Law of Flame Speeds,' claiming it to be applicable to all conditions of flame propagation. They added that "there is a considerable amount of evidence available that the relative speeds of the uniform movement of flame obtained under the specified experimental conditions are directly proportional to the speeds under other conditions, except during the detonation wave"; also, that the law of speeds applies to the rate of development of pressure in complex mixtures of gas with air (*Trans. Faraday Soc.*, **22**, pp. 301-306).

In a written contribution to the general discussion (*ibid.* pp. 314-320) I expressed doubts as to the general validity of this supposed 'law,' and stated that for some time past experiments had been in progress in my laboratories to test it from the point of view of the behaviour of complex mixtures of certain hydrocarbons with hydrogen and oxygen, containing an excess of combustible gases, and that we hoped to be able to publish a detailed account of the results of these experiments before the end of the year, when we would discuss further their bearing upon the 'law.'

The basis of the experimental test to which we have subjected the 'law' is one which the authors of it themselves have accepted. For in their recent paper at the Faraday Society (*loc. cit.* pp. 304-305) they said: (1) "that if a complex mixture is made by blending a number of mixtures of air with simple combustible gases all of which have the same speed of uniform movement of flame, then this complex mixture will also have the same speed of flame provided that all the mixtures are of the same type, all containing excess of oxygen or all containing excess of inflammable gas," and that (2) "an important deduction from the law of speeds is that during the propagation of flame in a complex mixture of combustible gas and air mixtures of the type we have just considered (all with the same speed of uniform movement of flame), the combustion can be regarded as involving the simultaneous but independent burning of a number of simple mixtures of the individual gases with air, in which the proportions of inflammable gas and air are such that each mixture, if burning alone, would propagate flame with the same speed as does the complex mixture." They also reported having found experimentally that complex mixtures of methane-hydrogen-and-air, containing insufficient oxygen for complete combustion, fulfil such conditions.

The experiments which have been in progress in my laboratories during the past two years upon the behaviour at atmospheric temperature and pressure of such complex mixtures as those of acetylene-hydrogen-and-oxygen, and of ethylene-hydrogen-and-oxygen, containing an excess of combustible constituents, are now completed, and the results thereof will in due course be communicated to the Royal Society. Meanwhile, I desire it to be known that in neither case have the observed flame speeds fulfilled the requirements of the 'law.' In the case of the acetylene-hydrogen-oxygen mixtures they diverged from it considerably; and for the ethylene-hydrogen-oxygen mixtures they were entirely inconsistent with it. Indeed, we have arranged an experiment, which can be shown to any one who will come to see it, affording visual evidence that the behaviour of such complex mixtures of ethylene-hydrogen-and-oxygen are irreconcilable with the requirements of the 'law.'

I am, therefore, convinced from my own experiments that, whatever degree of validity there may be in the conclusions which Prof. Wheeler and Dr. Payman have drawn from theirs, they are not universally applicable to all explosive mixtures, and therefore they cannot be vested with the authority of a natural law.

Rainfall Interception by Plants.

THE work of Marloth ("Results of Experiments on Table Mountain for ascertaining the Amount of Moisture deposited from the South-east Clouds": *Trans. S. A. Phil. Soc.*, 14, 403-408, 1903, and "Results of Further Experiments on Table Mountain for ascertaining the Amount of Moisture deposited from the South-east Clouds": *ibid.*, 16, 97-105, 1905) on the subject of deposition of moisture from the south-east clouds on Table Mountain, has attracted much interest in meteorological circles.

Marloth used two 5-in. gauges, one bearing a 12-in.-high frame of mesh wire and 4 vertical wire supports, through which seventeen Restionaceous stems were drawn, the other being an ordinary open gauge. In 56 days the control catch totalled nearly 4 in., the vegetation-screened catching nearly 80 in., representing an *interception gain* of about 1500 per cent. During ordinary precipitation the *interception gains* were 300-400 per cent., but during misty weather they rose to 1000-1200 per cent.

de Forest ("Rainfall Interception by Plants: An Experimental Note": *Ecology* 4 (4), 417-419, 1923), working in Maryland, employed three 3-in. gauges: the first bore a wire-mesh frame 12 in. high; the second bore a similar frame and in addition ten 12-in.-long imitation (tin) reeds, standing about 1·5-3 mm. apart, bent lengthwise to form interior angles of about 135°; the third served as a control. In four months (26 days measurable rainfall) the reed-clad gauge registered an *interception gain* of nearly 30 per cent.

The writer, working at Deepwalls, Knysna, South Africa (1725 feet elevation; Lat. 33·9 S., Long. 23·16 E.), has employed two 5-in. gauges 4 ft. high, standing within three yards of one another on the level ridge of an exposed hill. The first gauge bore a 12-in.-high frame of wire mesh identical with that used by Marloth; through the mesh four single branchlets of the broad-leafed conifer, *Podocarpus Thunbergii* Hook., were drawn, about thirty leaves (of 2-3 in. × ½ in.) being borne by each branchlet. The branchlets were arranged so that the foliage was held firmly in position, and the apex of each branchlet was placed ½ in. below the top rim of the frame, thus an evenly spread mosaic of leaves was exposed round the gauge. Care was taken to preserve the spread and density of the foliage-screen, the leathery, persistent nature of the latter necessitating very slight adjustment during the twelve months of the experiment.

The rainfall registered by the two gauges was as follows:

Month	Control Gauge.	Vegetation-screened Gauge.
June 1925	3·96 in.	7·95 in.
July	2·66	2·73
August	3·59	6·81
September	9·04	19·49
October	6·03	12·46
November	3·91	7·20
December	4·88	7·95
January 1926	3·37	6·34
February	*3·41*	*3·32*
March	5·62	10·54
April	3·43	6·60
May	2·12	3·17
Total	52·02	94·56
Percentage	100	181·7

Summarising: (1) In one year the control registered 52 in. only, the vegetation-screened, 94 in. (2) For every month except February 1926, the vegetation-screened gauge registered the higher catch—the reason for the higher catch by the control in February being that few hydrometeors occurred, the precipitation taking the form of normal and of heavy showers. (3) A classification of rain types for the period June 1925–May 1926, shows—

79 per cent. of the rains to have been of fine, misty nature (*Nebelreissen*).

13 per cent. of the rains to have been normal showers.

8 per cent. of the rains to have been heavy downpours.

(4) Detailed readings indicate that the greater catches registered by the vegetation-screened gauge occurred as the result of the *Nebelreissen*.

The *Nebelreissen* are responsible for the deposition of large amounts of moisture upon the exposed crowns of the Knysna Forest trees, and to a lesser but still appreciable extent upon the foliage of the two 15-ft.-high Macchia or *Fijnbosch*; the forests are usually dripping wet during *Nebelreissen*, while the ground immediately beyond their margins is comparatively dry.

The subject of *interception loss* due to vegetation has been studied by Horton ("Rainfall Interception": *Mon. Weath. Rev.*, 47, 603-623, 1919), and by de Forest (*loc. cit.*). Horton working in Albany, N.Y., with trees and field crops, concludes that rainfall interception represents a loss of rainfall which would otherwise be available to the soil, and shows that the interception loss is greater in forests than in fields. In the summer of 1918 he found the *mean interception loss* under eleven species of trees to be about 40 per cent of the total rainfall.

The writer has studied the interception loss in the Knysna forests as the result of the taking up of moisture by the foliage, branchlets, branches, and boles of the trees, and as the result of evaporation of thin films of moisture occurring on these parts. In one experiment two 5-in. gauges 4 ft. high were employed—the first being placed under canopy of climax high forest (*Podocarpus elongata* L'Herit. and *Olea Laurifolia* Lamk. being the dominants), the second being set under full exposure, about 200 yards distant. The elevation was 1500 feet, and the aspect southern. The results of the experiment may be summarised as follows:

(1) For the period February 1, 1923–January 31, 1925 the total catches by the gauge under canopy and by the control were 65·98 in. and 85·0 in. respectively; that is, there was an interception loss of about 22·4 per cent.

(2) The total number of days on which 0·01 in. or more was registered, was 58 days less under canopy than in the open.

(3) Interception losses were greater during Nebelreissen or fine rains, owing to the foliage, branches, and boles taking up so much of the moisture; heavy downpours lowered the interception loss considerably.

Observations are showing that while there is this well-marked interception loss below the trees, within their crowns the actual total catch of moisture is far greater (30-80 per cent) than at equivalent heights in fully exposed sites.

It is hoped that those interested in the fascinating subject of rainfall interception by plants will place on record any information they may have accumulated concerning the relative importance of interception losses and interception gains. JOHN PHILLIPS.

Forest Research Station,
Deepwalls, near Knysna,
South Africa, September 26.

The Occurrence of Helium and Neon in Vacuum Tubes.

IN a letter recently published in NATURE of October 30, 118, p. 625, Prof. Baly and Dr. Riding gave an account of their more recent experiments on the appearance of the rare gases in electric discharge tubes. Under certain conditions they found both neon and helium in the residual gas, and they record one instance in which pure helium was obtained. These results confirm their earlier observations, as well as those of Collie, Patterson, and Masson (1915). The authors incline to interpret their results as due to a disintegration by the electric discharge of the nitrogen atom, the experiments having been performed in mixtures of oxygen and nitrogen, or with nitride electrodes.

Whatever may be the true interpretation of these experiments, their importance cannot be denied, for they undoubtedly reveal a phenomenon in electric discharge work the significance of which has not hitherto been adequately appreciated. There can be no doubt that the results can not be interpreted as arising from a simple air-leak, for positive results have been obtained under a great variety of conditions, and elaborate precautions have been taken to avoid contamination from outside. Nevertheless, the possibility of the diffusion of atmospheric helium and neon through the walls of the apparatus, first suggested by Lo Surdo (*Atti Linc.* (5), 30, I. p 85, 1921), does not seem to have received the attention it deserves in the interpretation of such experiments, and it is the purpose of this note to indicate that the effect is by no means negligible.

That helium and neon diffuse through heated quartz and glass is a well-established fact, though most of the experiments on the phenomenon have been performed with these gases in a state of comparative purity, and at appreciable pressures. The effect is much greater with helium than with neon. According to experiments of Williams and Ferguson (*Am. Jour. Sci.*, 44, p. 2160, 1922), the permeability of fused silica glass to helium is proportional to the pressure and increases exponentially with the temperature, and with Pyrex glass at 610° C. the effect is about 5 per cent. of that with fused silica at the same temperature. Furthermore, O. W. Richardson and R. C. Ditto (*Phil. Mag.* (6), 22, p. 704, 1911) have shown that at 1000° C. helium diffuses from the air through fused silica more rapidly than neon.

In their remarkable work on the transformation of hydrogen into helium, F. Paneth and K. Peters (*Ber. d. D. Chem Ges.*, 59, p. 2039, 1926) have also directed attention to the passage of helium and to a lesser extent of neon through heated glass. Even at normal temperature they were able to detect the presence of helium in their apparatus after the lapse of about a week, their arrangement being so sensitive that they could detect about 10^{-8} c.c. of helium. For this reason, in experiments of long duration they immersed their apparatus in water, when the presence of helium was not detected even after a period reckoned in months.

In experiments by Dr. J. S. Hawnt and myself, it has frequently been necessary to test our apparatus for atmospheric contamination, and in the course of this work we have also established the diffusion at room temperature of helium from the air into our apparatus, which is constructed of glass, with an attached quartz discharge tube. Thus, after the apparatus had stood evacuated for a fortnight, during 36 hours of which part of the discharge tube was heated locally by means of a sand bath at 200° C, we found, after removal of hydrogen and absorption by charcoal, that the residual gas was helium, no trace of neon being evident The volume of helium (at N.P.T.) so obtained was greater than 10^{-7} c c, our apparatus being capable of detecting 10^{-8} c c. or less. In the spectrum of the excited residual gas the mercury lines and Hα were feebly developed, but the helium lines were strong, and the colour of the discharge was that characteristic of helium in the capillary of a vacuum tube containing helium at reduced pressure. The following helium lines were well developed: 6678, 5876, 5016, 4922, 4713, and 4471.

It is well known that in heavy unidirectional induction coil discharges in vacuum tubes, particularly at low pressure, the glass walls of the bulb surrounding the cathode become very hot Moreover, in heavy condensed discharges (with spark-gap) the capillary becomes strongly heated, whereas the bulbs remain relatively cool. In the latter case, also, if the pressure of the contained gas be increased, a greater spark-gap is necessary to get the same amount of heating in the capillary. Now these are precisely the conditions under which Baly and Riding have obtained helium and neon in their discharge tubes, and it seems practically certain that in experiments of from 60 to 100 hours duration helium in appreciable quantity, and to a lesser extent neon, will diffuse from the air through the heated parts of their discharge tubes. It would be interesting if the experiments were repeated with the bulb and the capillary respectively immersed in a jacket containing mercury or through which water was continuously flowing during the discharge. The non-appearance of the rare gases in such cases would be proof that these gases had previously diffused from the air into the discharge tubes. It should also be pointed out that by enclosing the discharge tube in an evacuated glass vessel the entrance of helium will not be prevented, for the double walls will probably both be hot at the cathode end in the ordinary discharge, and the diffusion will only be retarded owing to the greater thickness of glass through which the helium (and neon) must now diffuse.

Should the occurrence of the rare gases in electric discharge tubes really be due to their diffusion through the heated glass from the air, it is rather surprising that helium is not always more abundant than neon in the residual gas. It seems not unlikely that some other cause may also be involved in the case of neon, for neon is often present in greater quantity than helium.

Paneth (*l.c.*) has pointed out that glass has the ability of selectively adsorbing helium from a helium-neon mixture, and this may in part explain the occasional relative abundance of neon as compared with helium. A further contributory cause may be adduced from the fact that in a helium-neon mixture subjected to electric discharge, helium disappears more readily than neon, presumably due to absorption by the electrodes, sputtered metal, or the glass walls. Thus Claude (*C.R*, 156, p. 1317, 1913) found that with 1 per cent. helium in neon the helium disappeared by absorption during the passage of the discharge, whereas in a mixture containing 1 per cent. neon in helium the neon did not disappear.

A Possible Connexion between the Wave-Theory of Matter and Electro-Magnetism.

In de Broglie's theory a particle of matter travelling with velocity v has associated with it a phase-wave travelling with velocity c^2/v. It seems that this theory may have some connexion with Sir J. J Thomson's theory of moving lines of force if we interpret v as a velocity of the electric line and c^2/v as the velocity of the magnetic line.

In this theory, as I understand it, a possible velocity v for a line of electric force satisfies the equation

$$H=\frac{1}{c}[v \times E],$$

where E is the electric and H the magnetic force. A possible velocity w for a line of magnetic force is, on the other hand, given by the equation

$$E=-\frac{1}{c}[w \times H].$$

Eliminating H and making use of the equation $(w\,E)=0$ we find that

$$(v.w)=c^2.$$

When v and w are in the same direction, this equation gives $w=c^2/v$. In the later developments of Thomson's theory (see, for example, H. Bateman, *Phil. Mag.* vol. 34 (1917), p. 405), expressions of type

$$H_x=\frac{\partial(\psi,\tau)}{\partial(y,z)},\ E_x=\frac{1}{c}\frac{\partial(\psi,\tau)}{\partial(x,t)},$$

are adopted for the components of E and H and the equations of a moving line of magnetic force are

$$\psi=\text{constant},\ \tau=\text{constant}.$$

Adopting also expressions of types

$$A_x=\frac{1}{2}\left(\psi\frac{\partial\tau}{\partial x}-\tau\frac{\partial\psi}{\partial x}\right),\ \ldots\ \Phi=-\frac{1}{2c}\left(\psi\frac{\partial\tau}{\partial t}-\tau\frac{\partial\psi}{\partial t}\right)$$

for the potentials, we remark that if ψ and τ both satisfy de Broglie's equation

$$\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}-\frac{1}{c^2}\frac{\partial^2\psi}{\partial t^2}=\frac{m^2c^2}{h^2}\psi,\ h=\frac{h}{2\pi},$$

then we have the usual relation

$$\frac{\partial A_x}{\partial x}+\frac{\partial A_y}{\partial y}+\frac{\partial A_z}{\partial z}+\frac{1}{c}\frac{\partial\Phi}{\partial t}=0.$$

If we assume simply (P. A. M. Dirac, *Proc. Roy. Soc.*, vol. 112 (1926), p. 670)

$$\psi=e^{i\frac{E}{hc^2}(vx-c^2t)}f_1(y,z),\ \tau=e^{-i\frac{E}{hc^2}(vx-c^2t)}f_2(y,z),$$

$$E=mc^2\left(1-\frac{v^2}{c^2}\right)^{-\frac{1}{2}},$$

the electromagnetic field turns out to be independent of the time,[1] but according to the above rules the lines of magnetic force can be regarded as moving with velocity c^2/v parallel to the axis of x, and the lines of electric force with velocity v in the same direction. If our function ψ can be regarded as a constant multiple of Schrödinger's ψ and τ as its imaginary conjugate, then, whenever we have an expression such as

$$\psi = \Sigma A_n e^{2\pi i \nu_n \left(t - \frac{x}{c}\right)},$$

the only frequencies which appear in the electromagnetic field are the differences $\nu_n - \nu_m$ of the fundamental frequencies.[2] We are not bound, however, to make ψ and τ conjugate complex quantities. If, for example, we put

$$\psi = \frac{hec}{Er} e^{\frac{iEt}{k}}, \quad \tau = ie^{-\frac{iEt}{k}},$$

where r is the distance from the origin, both ψ and τ satisfy de Broglie's equation and we have

$$E_x = -\frac{ex}{r^3}, \quad E_y = -\frac{ey}{r^3}, \quad E_z = -\frac{ez}{r^3},$$

$$H_x = 0, \quad H_y = 0, \quad H_z = 0.$$

The field is thus that of a simple electric pole.

Patent Law and Unemployment.

THE writer of the article on the above topic has provided, in NATURE of November 13, p. 695, a very valuable graph of the number of British patents kept in force for the fourteen years' term, and has supplied useful figures of the number of foreign patents granted in Great Britain from 1900 to 1909; but I dissent from his conclusions. The former shows an almost continuous rise in the number of the fourteen-year enduring patents from 1897 onwards. This cannot be due to the retrospective action of the 1902 Act. It supports my contention that the rise is due to external industrial conditions. If the writer of the article compares his graph with the list of the numbers of foreign inventions patented here he will see that the rise or a fall in the latter is reflected in a corresponding rise and fall in the graph.

Hence I again urge that an official inquiry should be made to ascertain whether these foreign patents were taken out for the purpose of fostering or obstructing British industries. This is more material, as it is known that since the year 1900 or thereabouts British capital has gone abroad in increasing quantity (cf. Hobson, "Export of Capital"), and this fact, while it makes for national wealth, accentuates the problem of unemployment. I agree with the writer that foreign inventions patented here represent the cream of foreign inventive talent. I was wholly opposed to the foolish Act of 1919 which for a time acted as a deterrent to the foreign inventor. My contention is that if it is wished to induce the foreigner to introduce his industries here, we must stop threatening him and must offer him such better terms as will induce him to come over and help us.

E. WYNDHAM HULME.

Littlehampton, November 14.

MR. HULME'S contention that there is "an almost continuous rise in the number of fourteen-year enduring patents from 1897 onwards" can be tested numerically. For the period 1885 to 1896 the average number of such survivors was 498 per annum, the mean deviation being 4·9 per cent. and the maximum deviation 9·4 per cent. For 1899 and 1900 the figures are 509 and 508 respectively, and the deviation from the previous average, namely 2 per cent, was thus so well within the previous mean deviation that the rate of survival may be regarded as steady down to 1900 at least. Nor is the rise really great for the next two or three years. Practically the whole transition took place over the period 1904–1906, and by 1907 the figure had become so steady again that for the period 1907–1912 the mean deviation from the new average of 1210 was only 2·3 per cent., and the maximum deviation only 5·4 per cent. It is difficult to think of any cause for such a change other than the enhanced prestige conferred upon patents by the Act of 1902, as a result of increased confidence in their validity.

The rate of survival is no doubt affected by the number of patents granted to foreigners There are other factors, however, which swamp the correlation in question, and it does not seem to be very close.

Mr. Hulme more than any one else can claim credit for having directed attention in recent years to a principle which is in real danger of being forgotten, namely, the principle that the value of a patent system must be measured by its success in fostering the establishment of new manufactures within the realm. But surely if a capitalist is to risk his capital on a manufacture which has been patented, he wishes to feel some assurance that his patent is a valid one. In proportion as his confidence is increased in this respect will he be willing to risk the necessary outlay in experimental work, plant, organisation and publicity. He has to create a new demand; and he needs to be assured that when he has done so he will not be robbed of his reward by the competition which invalidation of his patent would make possible.

THE WRITER OF THE ARTICLE.

The Oogenesis of Lumbricus.

THE letters by Mr. L. A. Harvey and Prof. V. Nath in NATURE of November 27 and December 4 require comment. With regard to Parat's 'Vacuome Theory,' I have little of value to say. Some of my associates have a leaning towards the vacuome theory, and Prof. Nath does not mention Nassonov's Protozoa work, which is certainly in its favour. One of my most valued pupils, Dr. Bhattacharya, of Allahabad, after studying in Paris, embraced Parat's views, and naturally this has had some influence on me. In the oogenesis of Patella, a form investigated by Ludford, Woodger, Rodgers Brambell, and myself, it does seem that it is the sphere-substance and not a vacuole, which forms the fat globules. Reinvestigation of this form, in view of Parat's claims, might yield interesting results. If Mr. Harvey really wants to see Golgi bodies forming yolk and fat, I commend him to Patella, where the phenomenon is very clear.

I think that the evidence for Parat's views is getting stronger, but I do not care to commit myself to any more definite expression of opinion at the present moment. I consider that Prof. Nath's very interesting attempt to co-ordinate Parat's results, and his own valuable investigations on yolk formation, should be weighed carefully by future workers on the cytoplasmic inclusions.

Mr. Harvey is ill advised to reopen a controversy on his paper. I have no intention of repeating here the substance of our reply to Mr. Harvey's paper, which Dr. Nath and I have published in the recent issue of the *Q.J.M.S.* The reader of this letter should refer to that journal.

---

[1] This may be avoided by using the type of solution employed by L. de Broglie, NATURE, Sept. 25, 1926.

[2] This was suggested by the remark at the end of Schrodinger's paper, *Ann. d. Phys.*, Bd. 79 (1926), p. 734.

Now, regarding Mr Harvey's letter, it should be pointed out that my Saccocirrus work, the only paper published on annelid oogenesis before Mr. Harvey's paper, was merely quoted by him in the bibliography It is clear that Mr Harvey had not taken the trouble to read my work before he published his criticisms This was a pity

Mr. Harvey points out that his paper was more in the nature of a critique of the methods of argument used by my school. Years ago, when I had already published several papers in the *Q.J M S.* under Sir Ray Lankester's editorship, that great worker wrote to me a good many letters of advice. In one of these he said, "Collect as many facts as you can, avoid discussion." If Mr. Harvey will take this piece of advice to heart, it will be all to the good.

Mr. Harvey complains that I have called into question his technique and powers of observation. This is true. Mr Harvey quotes Dr. Cowdry. I know Dr. Cowdry's work: it is very fine, but it has no bearing on Lumbricus. Dr Cowdry has worked on vertebrate mitochondria and chondriocontes. I am dealing with the eggs of the common earthworm.

Mr. Harvey says that "Prof. Gatenby and his school are content to accept the view that yolk is a general term covering anything in the cell which cannot otherwise be identified." On the contrary, Prof. Gatenby and his school are *not* prepared to accept everything and anything, as Mr Harvey now realises clearly Mr. Harvey goes on to say, "Is it not time that cytologists made some attempt to bring the observations on oogenesis to as orderly state as are those on spermatogenesis?" Such an attempt has already been made by Rodgers Brambell, Nath, and myself. Mr. Harvey should read these papers *carefully*, and then sit down quietly and try to help by adding facts himself.

I am grateful to the editor of NATURE for an opportunity of seeing the letters of Prof Nath and Mr. Harvey. I have no wish to continue this controversy.

Chromosome Complements in Grasses.

THE hybridising and genetical study of grasses has reached a stage when information on their nuclear constitution is not only of general interest, but may also give guidance in elucidating problems of inheritance.

So far, we have had no recorded evidence of chromosome counts having been made in grasses, as apart from cereals.

I obtained, through the kindness of Mr. T. J. Jenkin, of the Welsh Plant Breeding Station, Aberystwyth, the use of grasses of known pedigree to carry out cytological investigations. This work was commenced in the summer of 1923 on *Lolium perenne* (Perennial ryegrass), *Lolium perenne* var. *multiflorum* (Italian ryegrass), and the hybrids derived from these two.

Anthers were selected as the organs most likely to yield the best results in the matter of chromosome counts. They were studied partly by means of microtome sections, and partly by means of the iron-aceto-carmine (Belling's) method.

The whole series of events in sporogensis was followed from the initiation of the meiotic divisions in the pollen mother-cell to the end of the homotype division.

Seven univalent chromosomes were so clearly distinguished in several phases of the reduction and homotype divisions that I can state with confidence that this number represents the haploid complement in *Lolium perenne*, *Lolium perenne* var. *multiflorum* and their hybrid progeny. The diagrammatic disposition of the seven bivalents on the nuclear plate, forming a regular hexagon with a chromosome at each angle and one in the centre, is remarkable It is of interest to mention that I found the divisions in the pollen mother-cells of the hybrids to be quite regular, except that 'lagging' chromosomes were occasionally found.

In studying mitoses in the root tips of *Festuca elatior* (probably var. *arundinacea*) (= Tall fescue), I discovered that the exact diploid number of chromosomes was difficult to determine, since the cell is comparatively small and the crowded chromosomes fill it to a great extent However, from my counts the full complement appeared to be in the region of forty.

The anthers of this grass were investigated later, and the reduced number of chromosomes was determined, with a fair degree of certainty, to be twenty-one.

From a preliminary study of *Festuca elatior* var. *pratensis* (Meadow fescue) I have strong evidence that the haploid number in this case is seven.

The iron-aceto-carmine method applied to the anthers of this grass was such a striking success that I was able to make a large number of counts in individual anthers.

It would thus seem that polyploidy obtains in genera of grasses, as in cereals.

The Planet Mars.

IN NATURE of November 13, p. 709, I notice the following sentence. "An objection frequently brought by M Antoniadi against the objective reality of the canals, based on their being drawn straight when far from the centre of the disc, is answered by a careful observation of the canal Amenthes-Thoth on October 19 and 20, 1924"

This passage scarcely represents the facts, for I have shown in numerous writings since the opposition of Mars in 1909 that, in the place of Schiaparelli's *canali*, the surface of the planet very often shows either (1) complex dusky streaks; or (2) jagged edges of half-tones; or (3) isolated, irregular dark spots. Amenthes-Thoth being a Schiaparellian marking, the probabilities, according to my views, are that, in its position, there exists an irregular streak. The Thoth I saw very broad, strong, and jagged in 1911, and insisted on its abnormal conspicuousness, considered it real, and discovered the fact that its changes are not seasonal—a fact that observation has fully confirmed since (See my Mars Report for 1911–1912, of the British Astronomical Association, pp. 116-117)

As the writer of the note on p. 709 refers to the 1924 appearance of the Amenthes-Thoth, and as I have represented that marking in 1924 as a winding, complex, dusky streak (*Bulletin of the Astronomical Society of France*, 1925, p. 82), it is only natural that it should obey perspective. The suggestion that the marking in question is illusive is thus completely answered.

Furthermore, Prof. Pickering did not mention me in connexion with his above observation, as the text on p 709 seems to suggest.

My position is perfectly clear: there is no geometrical network on Mars, since I have shown (1) that the linear canals vanish in a large glass when much more delicate detail is quite plain; (2) that they disobey the laws of diffraction; and (3) that they often disobey perspective Mr. E. W. Maunder, whose wonderful insight led to the theoretical solution of the canal question fifteen years before my observations of 1909, had already pointed out in 1894 that the linear 'canals' appear sometimes unduly straight near the limb of the planet; and I have further given a graphic demonstration of the illusive character of such appearances by the construction of spherical projections. I must continue therefore to refute any attempt to represent, as real lines, markings disobeying natural law, and I wish to express the view that the 'canal' question, in its present stage, is past serious scientific discussion.

The "H and K" Bands of Carbon.

IN discussing the negative bands of carbon, Deslandres mentions (*Comptes rendus*, 137, p. 460, 1903) the two strong bands λ2883·86 and λ2897·11 which "are very intense, are diffuse on both sides, are of a different structure and otherwise very curious," and suggests that they may probably be due to oxygen. These bands have also been noticed by Prof. Fowler while studying the comet-tail bands, but he makes no mention of them in his papers He calls them the "H and K" bands of carbon because of their striking resemblance to the two solar lines H and K. In a recent paper Johnson (*Proc. Roy. Soc.*, A, 108, p. 343, 1925) observes that each of these bands is resolved into two components, and he has allocated two of them to the regular negative band system. This allocation seems to be of a rather doubtful nature, for the structure of these bands is peculiar and they can be obtained alone, unaccompanied by the other members belonging to the same system.

While experimenting on the spectrum of neon under a low pressure, these two bands were prominently obtained on a photograph. The tube contained carbon and oxygen impurities, as was evidenced by the presence of the strong lines belonging to them. The bands were seen only in the uncondensed discharge, and no other bands were to be seen at all The structure of these bands is remarkable. Each consists of three lines, a central sharp line bounded on each side by a diffuse line, the less refrangible diffuse to the red and the more refrangible diffuse towards the violet. The writer had the opportunity of examining the old plates of Prof. Fowler and verifying the wave-lengths. In those plates, however, the resolution was not sufficient to warrant accurate measurements. The following table gives the wave-lengths of the lines measured on a plate taken with a large Hilger quartz spectrograph that gave a dispersion of about 14 Å.U. per mm. in this region.

Deslandres. λ I.A.U.	Johnson. λ I Å.U.	Present Measures. λ I.A.U.	ν (vac.)

The Anomalous Dilatation of Invar.

IN NATURE of November 6, p. 662, Prof. F. Zernike describes an experiment claiming to be a repetition of our dilatation measurements of invar. This experiment, however, presents considerable differences regarding the method and thermal circumstances used as well as the state of the metal.

The wire now used being 0·5 mm. in diameter has a section only 0·09 times the one used by us (diameter 1·65 mm.). Consequently, the time—about 3 minutes—during which the intermedial changes were observed by us (before contraction set in on heating) must have been a considerably reduced one. Further, on account of the wire being heated by the passage of an electric current, this time must be shortened still further. Now, such electric heating—in spite of giving necessarily a definite temperature gradient in a radial direction—may be all right for the later observations, at the very beginning, however, when a rather uniform temperature is indispensable, the temperature distribution along the specimen necessarily is a non-uniform one (say parabolic) This must reduce the intermediate dilatation as observed by us, and render the observation more difficult. The comparatively high stress of about 1 kgm. as applied by Prof. Zernike will also act in the direction of lessening the effect observable.

On the other hand, it is well known that the dilatation properties of a 36 per cent. iron-nickel alloy are dependent to a considerable degree of the thermal and mechanical treatment; it can scarcely be considered as invar when not in the original well-seasoned state. On account of this we deemed it necessary to investigate the ('geodetic') wire in its original state, using merely the heating (to 50°) necessary for the experiment. Prof. Zernike, on the contrary, has examined a wire which after the original treatment had been severely cold-worked, in one case "after annealing at a red heat." After such a treatment the alloy is certainly not strictly comparable to the original invar wire, as used by us.

In these circumstances we cannot consider that the experiments made by Prof. Zernike "in order to repeat" our work, really fulfil this purpose, and we await a repetition more nearly equivalent to our method before taking the work up again.

Science and the Press.

IN reference to the leading article on "Science and the Press" which appeared in the issue of November 27, it may interest readers of NATURE to know what action has been taken in Glasgow in this connexion. A publicity campaign, under the auspices of the local section of the Institute of Chemistry, has been in operation for the past four years, and during that time 125 articles of column length have been published at regular intervals in the *Glasgow Herald*. These articles deal with the applications of chemistry in a popular fashion, and several have been written at the special request of the editor. The evening papers have also opened their columns, and about 175 short articles have appeared there. The scheme is still in operation and has been eminently successful. The experience of the *Glasgow Herald* may perhaps influence other newspapers to make a special feature of similar popular scientific efforts.

W. M. CUMMING.

The Royal Technical College,
Glasgow, C.1, November 30.

Critical Potentials of the Vapours of Mercuric Halides.

STUDYING the losses of energy suffered by slow electrons in mercury vapour by the methods of Lenard (velocity distribution) and Franck and Hertz, we came across a rather sensitive arrangement for detecting the inelastic collisions of smaller probability (V. I. Pavlov, *Jour. Russ. Phys.-Chem. Soc.*, Phys. Sect., v. 58, p. 369, 1926). Applying this combined method to the investigation of the vapours of mercuric halides, we found for mercuric chloride at least four values for critical potentials: 1·6 v., 2·7 v., 3·9 v., and 6·6 v.; for mercuric bromide: 1·5 v., 2·9 v., 6·6 v., and 8·9 v.; for mercuric iodide: 1·4 v., 2·7 v., 6·2 v., and 7·8 v. The same method for iodine yielded the values. 1·2 v., 2·3 v., 3·8 v., 5·1 v, and 7·5 v. Some of these data seem to be in agreement with the observed absorption by the vapours of light of corresponding quanta.

It may be hoped that the results obtained will lead to the building up of a system of energy levels of the molecules investigated and will give some knowledge of the various possible ways of dissociation with excitation.

V. I PAVLOV.
A. I. LEIPUNSKY.

Physical and Technical Laboratory,
Leningrad, November 18.

Optical Excitation of the Vapours of Mercuric Halides.

IN the course of an investigation on the optical excitation of salt vapours I have found that vapours of mercuric chloride, mercuric bromide, and mercuric iodide of low density, when illuminated by the spark, give a bright visible fluorescence; this is green for mercuric chloride, blue for mercuric bromide, and violet for mercuric iodide. The fluorescence consists of a system of bands with a somewhat abrupt maximum of intensity at respectively 5600 Å.U., 5000 Å.U., and 4400 Å U., and there is a continuous falling of intensity down to about 4000 Å.U.

The lines which stimulate these bands are strictly confined to the following rather narrow limits: 1900-1850 for mercuric chloride, 2100-1900 for mercuric bromide, and 2200-2100 for mercuric iodide. A detailed analysis of the structure of these bands, together with further experimental work, will give, I hope, some information upon the underlying mechanism.

A. TERENIN.

Optical Institute, Leningrad.

Sir William Crookes and Spiritualism.

IN the leading article in NATURE of November 20, it is stated that Sir William Crookes closed the spiritualistic chapter for the rest of his life for reasons which, owing to the deliberate destruction of the necessary documents, it is impossible to gauge.

I am in a position to throw light on this matter, and as what I have to say is purely historical, and does not touch on the marvellous, it will perhaps not be considered to fall under the ban of the editorial closure.

Sir William Crookes, on a visit to my parents in August 1894, engaged in conversation with my grandmother, the second Lady Rayleigh, on this subject. I listened with attention. The conversation was substantially as follows:

Lady R. Have you had any recent spiritualistic experiences?

Crookes. No, unfortunately not. The difficulty is that I have not been able to get into touch with any suitable medium lately.

Lady R. Well, that is unfortunate; but after the wonderful things that you have seen perhaps you may fairly be satisfied.

Crookes. I do not know that. When one has had a good dinner one day, one none the less wants another the next day.

The last sentence is quite clear in my recollection.

RAYLEIGH.

Terling Place, Chelmsford, Essex,

Behaviour of Silicic Acid Gel during the Drying-up Process.

IN a note published in the *Proceedings of the Indian Association for the Cultivation of Science* (vol. 9, Part 4, p. 328, June 1926), I described an observation made by me more than two years ago (in April 1924), namely, that when silicic acid gel is treated with a concentrated solution of potassium chloride and is then allowed to dry up, the salt exudes from the surface of the gel in the form of thin white, glistening fibres. I attributed this to the pressure that is exerted upon the capillaries of the gel, as the gel continually loses water and experiences contraction. A photograph of the growth was also published there. It was further pointed out that an X-ray examination of those fibres of potassium chloride might reveal their true nature. As indicated before, this phenomenon seems to be very general, and should therefore be observable with various gels and salts.

The note referred to was written long ago, but its publication was delayed, as I intended to study the phenomenon further.

In a paper on the "Structure of Silicic Acid Gels," communicated by Messrs. Fells and Firth to the *Proc. Roy. Soc.* (112 A, Sept. 1926, p. 468), the authors describe interesting experiments on the same phenomenon. Apparently my previous note was not noticed by them.

The Reaction to Flea Bites.

PROF. E. A. BOYCOTT, in NATURE of October 23, says: "Some persons who are extensively flea bitten seem to become immune." This is, in my case, true of other insect bites. In January 1885 I suffered the most terrible agony from bites of Australian sand-flies (I do not know the specific name). Some seven years afterwards I was again in a sand-fly-infested neighbourhood and was completely immune from effects, and was so ever since.

In January 1906 I spent four or five days fishing in New Zealand, where I suffered misery from the bites of the New Zealand "sand-fly." (This is quite a different insect from its Australian namesake.) Returning again in January 1907 I suffered almost as much. I visited the same spot for four or five years later, and, though attacked as much as before, never felt any effects.

Similarly the mosquito, which was once a terror to me, now does no more than leave a painless mark. It is perhaps curious that the 'gruelling' I had from the Australian species has conferred immunity in Europe.

ERNEST I. ROBSON.

Oxford, November 2.

enable us to modify the processes of our bodies more in accordance with our wishes—to stimulate our faculties when we need high-tension work, but without evil after-effects; to relax them without the use of harmful soporifics. It seems clear that temperament, even more important than pure intellect in achieving success, is largely an affair of the balance of the various glands of internal secretion—thyroid, pituitary, reproductive, adrenal, and the rest. It may well be that the applied physiology of the future will discover how to modify temperament.

But I must close. Let me emphasise that while pure science will make discoveries so long as she exists, while technology will apply those discoveries so long as profit is to be made out of their application, it is in the long run the average man and woman who decide *how* that application shall be made. Whether the discoveries of science will in the ultimate event be beneficial, as those of us trust who believe in progress, or whether they are leading the human race to destruction, as many sincere and many far-sighted men assert—that will be decided by the use to which the human race decides to put them. In themselves, apart from their intense personal value to their discoverers, and to others on the plane of pure intellect, they are, like any other tool, neutral.

Developments in the Use of Echo-Sounding Apparatus.

THE use of compressional waves in water for the measurement of the depth of the sea beneath a vessel now lacks the novelty which it possessed some years ago, when practical schemes for using them in navigation were first put forward. Briefly, all such schemes reduce to three essential parts—the source of the compressional impulse, the receiver of the echo from the ocean bed, and the mechanism for recording the time interval between the emission of the original disturbance and the moment of receipt of the echo, or, in some cases, the direction of the returning wave front. Small explosive charges dropped into the water, automatic hammer-blows on diaphragms, and diaphragms which are caused to vibrate electrically are used as sources of compressional disturbances within the audible range and form parts of actual sounding sets which are obtainable commercially. Microphones attached to diaphragms exposed to the sea are in general use for receiving the echo and for transforming the sound energy into electrical power. Various mechanisms, some of which are simple and ingenious, while others appear, from their descriptions in technical papers, to be unduly complicated and too delicate for continued sea-going use, are favoured by different firms who have embarked on the manufacture of echo-sounding gear. A typical echo-sounding apparatus for use in shallow water was described in NATURE in an article dealing with the use of the method in navigation.[1]

All the systems of sonic echo sounding covered by the remarks in the preceding paragraph involve the creation of an audible disturbance, but there is one system in which the initial disturbance has a frequency which lies above the upper limit of the range of frequencies audible to the normal human ear. The practical form of this apparatus is described in a recent publication issued by the International Hydrographic Bureau,[2] and the principles of its operation have already been described in these columns,[3] where it was observed that this 'supersonic' or 'ultra-sonic' system was of great scientific interest. It is clear that much skill and ingenuity have been expended in the design of the mechanisms embodied in the gear as now manufactured.

For sounding installations from which nothing more is demanded than an accurate measure of the depth of shoaling water beneath a ship, it appears that sonic systems are capable of answering navigational requirements, but the merit of the supersonic system lies in its ability to locate comparatively small objects, such as wrecks or rocks, in shallow water. This advantage is gained by the supersonic system because the energy is transmitted through the water in a beam the direction of which can be altered, whereas the sonic impulses are more nearly in the form of spherical waves spreading through the water without marked directionality. The supersonic gear cannot, however, be relied upon to detect projections which are small in comparison with the breadth of the beam, and at great depths therefore this system cannot be expected to show much greater power than the sonic gear to resolve discontinuities in the depth of water, unless either the size of the oscillator, or the frequency of its oscillation, is increased so as to make the beam sharper. There are limits beyond which both of these courses become impracticable.

Judging from published descriptions of the supersonic gear as manufactured by the Société de Condensation et d'Applications Mécaniques, the equipment must be decidedly costly and must require skilled operators and attention in case of defects. For these reasons it is to be expected that the simpler and less costly forms of sonic gear will be more popular and that the use of the supersonic apparatus will for some time be limited to special purposes where the sonic gear fails. On the other hand, disappointments with the echo-sounding gear must be anticipated and be looked upon as certain to come. The final form of every new thing is reached by stages, and it may be years before the defects which are bound to occur in existing echo-sounders are all eliminated and so great a mass of evidence for the reliablity and usefulness of the gear becomes available that the wholesale adoption of this invention is inevitable. It is scarcely necessary to quote examples in which events have followed a course similar to that which may be anticipated in the case of echo sounders, but the gyro-compass and the use of directional wireless in navigation may be mentioned. Both these aids to navigation 'hung fire' for years and the gyro-compass is only now coming into general use, while the application of directional wireless is still somewhat under a cloud, owing to errors in the readings taken, which are partly due to the effect of the ship's structure on the apparatus and partly to imperfectly understood effects such as the apparent coastwise refraction of the electric waves. One cannot blame the experienced navigator, upon whom the onus of a disaster falls, if he is chary about accepting the claims which well-informed people are making for sonic-sounding gear, but one is fully justified in urging that the method should not be condemned on the evidence of a few initial failures.

[3] NATURE, May 9, 1925, pp. 689-90.

Further experiments, of which no detailed description has yet been observed in the English scientific press, have been made in France by the Société de Condensation et d'Applications Mécaniques with a supersonic transmitter for guiding ships along a channel. In these experiments, according to newspaper reports, a supersonic oscillator is fixed at the entrance to a channel and arranged so that its beam may be projected horizontally and rotated in azimuth. In order to obtain the bearing of a vessel, the transmitter may, as in the well-known wireless beacon system, be rotated at a constant rate, or may be made to emit signals corresponding to the bearing of the oscillator. Alternatively, wireless signals might be used to indicate the instantaneous bearing of the beam. A vessel entering the channel would be swept intermittently by the beam and would thereby be informed of its bearing with respect to the transmitting station. The distance of the vessel from the transmitting station could easily be obtained by recording in the ship the difference between the times of arrival of the wireless and sound signals, the principle being the same as that which is used in the radio-acoustic system of position-finding at sea.

The value of such an installation in fog is obvious, for the underwater beam does not suffer from those extraordinary effects of reflection and refraction which make aural observation of the direction of a fog signal or siren station so unreliable in these circumstances. On the other hand, it would be necessary to fit each vessel using the system with a special receiver of high-frequency oscillations, since hydrophones and other instruments which are suitable for use with submarine bells or oscillators of the Fessenden type, are useless as detectors of the ultra-audible vibrations which compose the supersonic beam. The press accounts of the actual system used by the Société de Condensation et d'Applications Mécaniques are not very precise in the description of the manner of obtaining the ship's position relative to the transmitting station, but it is clear that the position might be obtained without the use of any underwater gear in the ship itself. The ship, in fact, acts as reflector of the supersonic beam, so that the operator of the shore station, hearing an echo, would know that a ship was on a certain bearing from him, while the range of the ship can clearly be deduced by the measurement of the 'echo-interval' as in ordinary depth sounding. This information could then be signalled to the ship by wireless telegraphy.

Judging from the cold reception which was given to the leader gear system by shipping companies, it is feared that development of the underwater beam system of guiding ships into harbour is unlikely to be hailed with enthusiasm, and that masters of vessels will prefer to wait for clear weather rather than trust the indications of apparatus of which only a part is under their immediate control. The difficulties which stand in the way of the general adoption of any new schemes such as these are undoubtedly great, and the real trouble is to form a body of opinion in favour of their general use.

Echo-sounding gear of the sonic type has been used also for the determination of the height of an airship above the ground in fog or darkness. The apparatus which was tried for this purpose in the ZR.3 before her journey across the Atlantic in 1924 was almost a replica of that which is used in one of the commercial systems of sonic echo sounding. The source of sound was a small explosive charge, and the time interval was recorded by a spring-driven wheel which was started and stopped by the outgoing shock and the returning echo respectively. It is clear that a machine which is capable of giving the pilot of an aeroplane or airship a continuous record of his height above ground would add greatly to the safety of aerial navigation, and experiments which have already been made indicate the possibility of attaining this end. It is probable that any apparatus which proves suitable for underwater sounding would require to be redesigned before being applied to aircraft, not only because of the necessity for cutting down weight, but also because diaphragm oscillators of the kind used at sea are incapable, when working in air, of delivering enough energy to be effective over any useful distance. The explanation of this is, of course, similar to that given by Stokes, in his classical paper on the communication of vibrations from a vibrating body to a surrounding gas, of Leslie's observation, made in 1837, that the sound of a bell vibrating in hydrogen is exceedingly feeble compared with the sound of the same bell vibrating in air.

Apart from its use as a navigational instrument, sonic-sounding gear has already been found valuable in making rapid hydrographic surveys in deep water. A large number of 'sections' have been made during the past year by vessels of the United States Navy in the course of ordinary voyages, and the results are believed to be in good agreement with charted depths when comparison is possible. The British Admiralty has made a fresh survey of the Challenger Bank using the Admiralty sonic-sounding installation in a survey vessel, and it is understood that a deep-water sounding set has been fitted in a recently built cable-laying vessel for oceanic use.

As an aid to hydrographic, hydrological, and fishery research the sonic sounder has already proved its importance, and it is noted that the German Research Vessel *Meteor* was equipped with no less than four sets of echo-sounding gear. A recently published account[4] of rather less than eight months' work in the Atlantic shows that some twenty thousand soundings were taken, the maximum depth recorded being 6110 metres. In a series of 89 comparisons between echo and wire soundings, the mean depth was 3420 metres and the wire sounding was, on the average, 2·2 per cent. greater than the echo sounding. This discrepancy may be due in part to drift and sag of the sounding wire, or, more probably, to the fact that the echo does not in general return from a point directly beneath the sounding vessel. This point is dealt with in the two paragraphs which follow. Since the echo-sounding gear is really a time-measurer we also require to know, for great accuracy, the velocity of sound in the different layers of water, between the surface and the bottom, through which the sound passes. This velocity will not differ markedly from that at the surface, but it will be affected to a calculable extent by changes in salinity, temperature, and the alteration in compressibility at great depths.

News and Views.

FOR the meeting of the British Association which is to be held in Leeds on August 31-September 7 next year, under the presidency of Sir Arthur Keith, the following sectional presidents have been appointed: Section A (Mathematical and Physical Sciences), Prof E. T. Whittaker; Section B (Chemistry), Dr. N. V. Sidgwick; Section C (Geology), Dr. Herbert H Thomas; Section D (Zoology), Dr. G. P. Bidder; Section E (Geography), Dr. R. N. Rudmose Brown; Section F (Economics), Prof. D. H. Macgregor; Section G (Engineering), Sir J. B. Henderson, Section H (Anthropology), Prof. F. G. Parsons; Section I (Physiology), Dr. C. G Douglas; Section J (Psychology), Dr. W. Brown; Section K (Botany), Prof. F. E. Fritsch; Section L (Education), The Duchess of Atholl, M.P.; Section M (Agriculture), Mr. C. G. T Morison. Notices are being issued for meetings of the organising committees of the sections to take place at King's College, Strand, by kind permission of the Principal, on January 7 at 12 noon, to consider the programme for the Leeds meeting

NOT so long ago, very considerable claims were made for a new treatment for cancer devised by Prof. W Blair Bell, of Liverpool. This claim was the outcome of work done by the Liverpool Cancer Research Organisation, of which Prof. Blair Bell is the Director. Recently a good deal more has been added to our knowledge of the new treatment by a discussion on the subject at the British Medical Association held at Nottingham in the summer and published in the *British Medical Journal* of November 20. While it is too early to make categoric statements of the value of the treatment, Blair Bell and his co-workers seem to have emphasised some facts which, if not altogether new, are at any rate confirmatory of the work of others. It is supposed that cancer or other malignant growths really represent a de-differentiation of the cells with a return to an embryonic type This, of course, is not a new idea, and has indeed been the current teaching for thirty years or more. The embryonic type with which Prof. Blair Bell compares the cancerous tissue is the trophoblastic mass which covers the chorionic villi of the developing embryo. The comparison is valid in that both the syncytium and malignant cells have a destroying effect on the tissues. Prof. Blair Bell suggests a closer analogy, as both have a similar morphological and chemical structure. He conceives malignant new growth to be a state induced by oxygen starvation supervening on injury to the cell itself or the neighbouring blood supply, and that the return to the trophoblastic state is to enable the cell to survive.

As there appears to be an affinity of embryonic cells for certain lead compounds, Prof. Blair Bell was induced to try preparations of the latter in the treatment of cancer. The exact preparation of the lead suspensoid is now published, and it is claimed that the intravenous inoculation of this agent has led to the arrest, disappearance, or cure of some undoubted malignant growths. Many who have seen Prof Blair Bell's cases agree with him that this is true. The treatment is most drastic and the mortality heavy. Apparently the mode of operation of the lead is to induce necrosis or other regressive changes in the tumour tissue, and while this is going on there may be severe or fatal injury even to normal tissues. Dr. L. Cunningham, the Assistant Director of the Liverpool Cancer Research Organisation, has tabulated the results of 227 cases treated by lead. Of these, 50 died before treatment was completed and 106 died after treatment. In 10 the disease was said to be completely arrested and 31 were "believed cured." He says that "lead is undoubtedly of value in the treatment of malignant disease, either alone or in conjunction with other methods; but we feel not only that something better may be found in the near future but that our preparation is imperfect"

AMONG the names of astronomers famous as the discoverers of comets is that of Giovanni Battista Donati, the centenary of whose birth at Pisa falls on December 16 of this year. Entering Florence Observatory at the age of twenty-six years, Donati became assistant to Amici, and in 1864 was appointed Director, a post he held until his death at the early age of forty-six years. During the years 1854–1864 he discovered six comets, that first seen on June 2, 1858, now bearing his name. The period of this comet is 1950 years, and its next appearance will take place in the year 3808. Donati was also well known for his early studies of the spectra of stars He observed the total solar eclipse of July 1860 at Torreblanca, Spain, and the same year began his studies in stellar spectroscopy. He indicated the feasibility of a physical classification of the stars, and in 1864 discovered the gaseous composition of comets. In August 1873 he was seized with cholera while attending the International Meteorological Congress at Vienna, and died on September 20 a few hours after his arrival home at Arcetri.

THE latest news to hand of the Dutch-American Expedition to explore Dutch New Guinea under the auspices of the Smithsonian Expedition furnishes some probable indications of the extent and value of the results which are likely to accrue from this penetration of the unexplored belt of forty miles of jungle which separates the Snow Mountains from the sea. Dr. Matthew W. Sterling, the leader of the expedition, expected to reach the mountains in August. The work accomplished by the expedition, which at the time of writing was considerable, especially in mapping much unknown territory and numerous river routes, was to a great extent due to the use of the aeroplane. This machine acted as the scout of the expedition and saved much time and expenditure of labour by its preliminary reconnaisances of the route. It did much survey work as well. Unfortunately it has been put permanently out of action by the effect of climatic conditions, but not before it had practically ensured the success of the expedition. Large collections of plant and animal life, as well as of ethnographical specimens, have been made. The natives were nervous and not uniformly friendly. Villages were sometimes found to have been deserted on the approach of the expedition. The only implements and weapons in use by the natives are of stone and bone. No metal is known.

IN view of the rising tide of Fundamentalism in the Protestant Churches of America, it is important to note that a certain number of priests in the Roman Catholic Church have conducted important researches in various branches of natural science without interference from the ecclesiastical authorities. In an interesting article in *Truth and Freedom* for October, Dr. J. J. Walsh supplies a number of examples. In the first place, there was the Augustinian monk Mendel, whose researches may be said to have created the new science of genetics. Then there is the German Jesuit, Father Wassmann, one of the most distinguished entomologists of our day. The present head of the Vatican Observatory in Rome, Father Hagen, S J., is the author of an atlas of variable stars, while the seismographs with which many Jesuit colleges are equipped have contributed much to scientific knowledge. Sir Arthur Keith, in a recent article in an American magazine, has told the story of a young priest, Father MacEnery, who was an important pioneer in the science of anthroplogy a hundred years ago, "working like a navvy to reach the things he prized." How the geological records might tally with Genesis did not trouble the chaplain of Tor Abbey Since his time many priests have taken a serious interest in palæontological and archæological anthropology, and in a recent number of the *Forum* (June) Prof. H. F. Osborn has named a dozen French, Belgian, German, and Spanish priests who have done valuable work in this department Prof. Osborn actually dedicated his "Men of the Old Stone Age" to two priests, the Abbé Breuil and Father Obermaier.

THE fact is that between natural science and religion in general there is really no quarrel, in spite of the Fundamentalist panic. Where there does seem to be a certain conflict is between the results of literary and historical criticism and some of the traditional dogmas of Christianity Here it can scarcely be said that the ecclesiastical authorities allow freedom of research to those under their control. When the Abbé Loisy, professor of Hebrew at the Institut catholique of Paris, dealt on scientific lines with the Canon, the religion of Israel, and the Babylonian myths behind the early chapters of Genesis, it cost him his chair In 1907 this scholar was excommunicated, and the same fate befel the English Jesuit Tyrrell Even the great historical scholar Mgr. Duchesne has had to walk warily. His examination of the legends which attached to the great French churches gave offence, while his "Étude sur le Liber Pontificalis" (1877) barely escaped the 'Index.' No doubt an institution has to preserve its integrity, but historical controversies cannot really be settled by disciplinary measures, any more than can controversies in the natural sciences.

THE Rev. J. C. Herrick, College of Mount Saint Vincent, City of New York, in a letter raises the question of the proof of the conservation of mass and energy. He writes: "Lavoisier proved the constancy of mass by the use of the balance" and therefore assumed "the constancy of the mass of his weights," while Joule in his work on the mechanical equivalent of heat also assumed that mass is constant. Mr. Herrick's argument arises from an incomplete statement of the experiments. The only assumption made by Lavoisier and by Joule is that mass does not vary *with time*. Assuming the truth of this fairly obvious proposition, Lavoisier showed that mass is not altered *during chemical combination*, and this result has since been confirmed by Landolt, who showed that the variation of mass as a result of chemical combination cannot exceed some extremely minute fraction of the whole. Joule's experiment merely showed that a given amount of work liberates a given amount of heat There is no absolute proof that the heat liberated might not be due to the destruction of a minute quantity of matter, but there is no shred of evidence to justify the supposition that by merely stirring water with a paddle the molecules can be destroyed.

THE chief point emphasised in a paper on "Surface Indications of Petroleum," read by Mr. A. Beeby Thompson at the Institution of Petroleum Technologists on October 6, was the invariable necessity of interpreting all surface indications of oil in terms of geological environment. Too often is the oil-show, asphaltic rock or seepage, or mud-volcano made *per se* the sole reason of commercial exploitation, and only too often has such adventure proved disastrous. Petroleum at the surface, in whatever form, obviously implies, and frequently does actually indicate, wastage, especially of valuable light constituents; such wastage may be on quite a large scale and may signify the penultimate, if not the ultimate, phase of widespread inspissation, clearly, from an economic point of view, storage and not escape is the obvious desideratum The subject of the paper is by no means new, nor was its treatment; there is, perhaps, nothing new which can be said, the substance of the paper being familiar to oil technologists from practically every text-book concerned with the geology of petroleum, but it at least provoked an interesting discussion, if at times slightly critical of the author's text.

BOTH Mr T. Dewhurst and Prof V. C. Illing, in the discussion on Mr. Beeby Thompson's paper, voiced the urgency of geological criteria in all investigations of surface indications, and Prof. Illing rightly deplored the author's use of the term 'metamorphosed' as applied to ozokerite, in view of the more precise geological meaning attaching to that word. In discoursing on the oil indications of the Gulf Coast fields of America, the author omitted any mention of the controversial substance 'paraffin dirt,' which, as Mr. H. B. Milner pointed out, had been the cause of the loss of large sums of money spent on exploiting this type of evidence. Dr. A. Wade was mildly discursive on the mud-volcanoes of Australia, and he also directed attention to the care needed in diagnosing wax 'indications' of paraffin base oils; unlike mining, the 'salting' of an oil prospect is a rare and difficult practice, and his warnings anent mutton fat and refinery wax were not without interest or humour. Another example of dubious indication was given by Mr. J. Romanes in connexion with bitumen occurring in some of the Quaternary deposits of the Guianas; the possibility of sea-borne material transported from Trinidad cannot be denied, a similar case occurring in the Falkland Islands, implying derivation from the Argentine. The author concluded his paper with a résumé of the coal-oil (carbon ratio) hypothesis, scarcely relevant to the more tangible subjects with which he had previously dealt, but he made no reference to Dr. Murray Stuart's recent contributions to this controversial problem.

PROF. J. L. MYRES, Wykeham professor of ancient history, University of Oxford, has been appointed Sather professor of classical literature for 1926–7 in the University of California. He is to spend the greater part of the semester beginning next month at Berkeley, lecturing in the Department of Classics, and also delivering a public course under the title "Who were the Greeks?" which will be published by the California University Press. On his way to Berkeley he is to attend the Philadelphia meeting of the American Association for the Advancement of Science, as representative of the British Association, and to give a public lecture on the "Geographical Surroundings of Greek Civilisation." He also hopes to attend the meeting of the American Historical Association at Rochester, and has promised to speak to the classical students at Chicago, on his way through.

THE registration of Imperial Chemical Industries, Limited, was formally completed on Saturday, December 4. The company has been registered with an authorised capital of 65,000,000*l*. As has already been announced, if all the shareholders of the merging companies exchange their shares for shares in the new company, the issued capital will be 56,802,996*l*. Amongst the objects of the company are acquiring or holding shares in Brunner Mond and Company, Ltd.; Nobel Industries, Ltd.; the United Alkali, Ltd.; and the British Dyestuffs Corporation, Ltd. The first directors of the company will be: Sir Alfred Mond (chairman), Sir Harry McCowan (president and deputy chairman), Lord Ashfield, Sir John Brunner, Mr. G. C. Clayton, Mr. H. J. Mitchell, Mr. Henry Mond, Sir Max Muspratt, Mr. J. G. Nicholson, Lieut.-Col. G. P. Pollitt, The Marquess of Reading, Sir Josiah Stamp, and Mr. B. E. Todhunter. The company has the biggest initial capital of any company hitherto registered in Great Britain.

NOVEMBER rains were a very special feature of the autumn this year in England and much prominence has been given to it in the *Times*. The Meteorological Office in its summary of the weather for November states that one of the outstanding features was the abnormally heavy rainfall experienced in many districts. At Shanklin it was the wettest November since records began in 1906; at Ross-on-Wye it was the wettest since 1888; and at Kew Observatory it constituted an easy record in November for sixty years. The total for the month was 5·12 in., which is 2·91 in. more than the average, with the exception of October 1923, when 5·32 in. fell, it was the largest total for any calendar month since September 1918. Rains were of frequent occurrence throughout the month, few days having no rain.

THE annual report of the Meteorological Committee to the Air Council for the year ended March last has recently been published (M.O. 288; London: H.M. Stationery Office; 2*s*. net). The report reviews the seventy-first year of the Meteorological Office and the sixth year in which the cost has been borne on Air Ministry votes. Considerable reorganisation of the work amongst the Divisions of the Office has been undertaken. Weather forecasting, weather broadcasting, and climatology have all shared in the changes. The magnetical work formerly carried out at Kew Observatory has been transferred to Eskdalemuir Observatory, and the seismological work from Eskdalemuir to Kew. The changes in the reorganisation will materially affect the efficiency of the work, and so react on the usefulness of the Office to those who need its services. Weather messages are supplied for issue by the British Broadcasting Company. It is shown that in the five years 1921–22 and 1925–26 the inquiries for special forecasts have doubled, increasing from 1914 to 3845 in the year under review. Data for air navigation form an important part of the work of the Office. The Marine Division shows considerable activity, an old difficulty is still experienced, and it is mentioned that renewed efforts are made to obtain an increase of observing ships in Pacific trades. A revision of the Admiralty Wind Charts of the World for the use of H.M. Fleet has been commenced. In the Forecast Division a gazetteer of telegraphic reporting stations has been almost completed. An inquiry is in progress into the relation between upper air temperature and the occurrence of thunderstorms.

REFERRING to the paragraph on the Rev. Edmund Gunter in NATURE of December 4, p. 813, Dr. R. T. Gunther writes from Magdalen College, Oxford: "Any account of Edmund Gunter's inventions should, I think, include the form of slide-rule designed by him which was widely known as a 'Gunter.' To him too are due the words *cotangens* and *co-sinus*, from which we get the familiar abbreviations of *cot* and *cos*. I have lately added models of his improved forms of cross-staff and cross-bow to the Lewis Evans collection, so that his scientific inventions are now for the first time almost completely represented in a modern museum. His work had a great influence on the methods of the next generation."

WE are indebted to Prof. Hugh S. Taylor, of Princeton University, U.S.A., for pointing out an error in the article on "The Reported Conversion of Hydrogen into Helium" (NATURE, October 9) on page 526, col. 2, 8 lines from bottom. The statement that the residual gas, after 12-hours' contact between

Research Items.

Egyptian Antiquities from Southern Russia.—Two communications in *Ancient Egypt* for September deal with Egyptian antiquities which have been found at various times in the course of excavations in southern Russia. Militza Matthieu describes scarabs and other objects found on the northern coast of the Black Sea and at Olbia in 1902, 1911, and 1914. These scarabs are of soft paste, coloured light blue or light yellow, usually right through, and of simple form They have striking analogies with scarabs found at Naucratis. In the same tomb in which five of the scarabs were found at Olbia were three pendants, two representing lions stretched out on a rectangular base, and one a ram's head. Similar pendants are also found at Naucratis, while two of the Black Sea scarabs show a lion with solar disc, exactly similar to a lion and solar disc pendant from Naucratis. In the tomb at Olbia Prof. Pharmakovsky also found black-figure vases, Rhodian, Miletian, and Naucratite ware, pottery, and glass beads. The second communication, by Prof. Zakharoff, describes a fragment of a crown of Osiris found in the Sloboda Nedvigovka (ancient Tanais) near the mouth of the Don—exact place and circumstances unknown. It is a fragment of bronze described erroneously in the Russian Historical Museum Catalogue of 1893 as an ornament of Scythian type It is flat, broken at the top, and on its right side has a uræus, with solar disc on its head The front of the uræus is ornamented with enamel in six cavities. The tail is interlaced with the horns of a ram It may be supposed to be part of a feather crown to be put on a figure of Osiris. It is unique in southern Russia. Similar crowns are shown in the Catalogue of the Cairo Museum, vol 1.

The Antiquity of Man in America.—In the *Scientific American* for November, Mr. Harold J. Cook, who discovered the tooth of Hesperopithecus in the Lower Pliocene deposits of Nebraska, replies to arguments put forward in the July issue by Dr. Aleš Hrdlička against the high antiquity of man in America. Mr. Cook argues that the 'modern' character of the skulls for which antiquity has been claimed may be due to the fact, familiar to palæontologists, that species of vertebrates may remain unchanged over long periods. Man may have remained unchanged physically and structurally in America for thousands and thousands of years No one can say, except in the most general terms, what were the conditions propitious to migration from Asia during glacial times, but conditions which made it possible for the bison and other animals of Asiatic origin to migrate should also be favourable to man. From known evidence it appears that in recent geological times both animals and man have migrated in successive waves. This long-drawn-out process has produced a degree of hybridisation which makes the anatomical evidence difficult to interpret with certainty. Further, the many Indian stocks exhibit as many great differences as characters in common, so that wide differentiation or homogeneity among them depends upon which characters are stressed The discovery some months ago of stone arrows and spear points associated with a buffalo skeleton at Colorado, Texas, gives definite positive evidence of the presence of man in America in Pleistocene times. The skeleton was buried under eighteen feet of old Pleistocene gravels; it was undisturbed, and it belonged, not to the living American bison species, but was of an Asiatic or Indian type not known in America, and it was associated with the bones of extinct mammals known from other sources to be of Pleistocene age. Associated with the 'buffalo,' and under the bones, were three stone implements. All the relics were clearly contemporaneous In the lower Pliocene age, a warm climate which extended to Alaska offered ideal conditions for migration by way of Bering Straits over a temporary elevation, and especially for anthropoid stocks or early man. That such stocks did enter has been shown by the discovery of the tooth of Hesperopithecus, which antedates the classical Anthropopithecus.

Craniometrical Data of an Immature Skull of a Female Chimpanzee.—Dr. E. Warren (*Ann. Natal Mus.*, vol. 5, pt. 3, 1926) has made careful measurements of an immature skull of a chimpanzee with the express purpose of placing on record data which could be used for comparison with the Taungs fossil anthropoid, Australopithecus. From his measurements and observations the author concludes that the young chimpanzee skull is appreciably less human than the Taungs skull, and therefore the peculiarities of the latter cannot be explained by its immaturity. He supports the contention that the Taungs skull exhibits a distinct advance on the living anthropoids in the direction of man, but the relative smallness of the brain would appear to indicate that it is considerably nearer to the living anthropoids than to man himself.

Experiments with Intestinal Protozoa.—Prof. R W Hegner records (*Amer. Jour. Hygiene*, 6, 1926, pp. 593-601) observations which show that the active stages of *Balantidium coli* from the pig are able to withstand conditions in the stomach and small intestine of the guinea-pig and may reach the cæcum of the latter, apparently unharmed, within one hour after ingestion. The active stages of *Trichomonas caviae* and *Chilomastix intestinalis* from one guinea-pig may pass through the digestive tract and reach the cæcum of another unharmed. The active stages of *Giardia canis* from the dog are able to live for considerable periods in the stomach and small intestine of the guinea-pig, and were found to be more numerous in that portion of the small intestine (6 in to 24 in. beyond the stomach) which seems to be their optimum habitat in normally infected animals Possibly it is the nature of the secretion in this region which causes the giardias to attach themselves to the epithelium by means of their sucking discs The active stages of *Endamoeba histolytica* are not quickly killed in the stomach and small intestine of the guinea-pig, but remain alive and mobile for at least an hour Infection by these trophic stages is probably not usual in Nature; the cyst stage is more often concerned in transmission, and methods of control should as heretofore be directed against this. *Trichomonas hominis*, which does not form cysts, is, however, present in about 3 per cent of the population, and infection appears to be by the trophozoite stage, entering by way of the mouth

The Digestive Diverticula in Lamellibranchs.—Dr. C. M. Yonge (*Trans. R. Soc Edin*, Vol 54, No. 15, 1926) has investigated the structure of the digestive diverticula—blind tubules which open into the stomach by ciliated ducts—in thirty-four species of marine lamellibranchs. The tubules have been stated to exhibit three kinds of cells, but Dr Yonge finds only one type. The cells when young stain darkly, but when older are very vacuolated and contain large numbers of coloured granules which disappear after starvation. In fresh material, long, retractile cilia were seen on the tubule cells in a number of the species and are probably present in all. When lamellibranchs are fed with iron saccharate in suspension, this is found later lying in large vacuoles in the cells of the tubules but is afterwards passed on to the amœbocytes. The manner in which particles are taken in, and the presence of digestive enzymes in extracts of the diverticula, point to the occurrence of intracellular digestion. There is no evidence that the cells of the tubules secrete, the presence of enzymes in the stomach can be accounted for by the dissolution of the crystalline style and the occurrence of great numbers of phagocytes free in the lumen. The diverticula provide the extensive surface characteristic of the alimentary systems of animals which possess intracellular digestion, while as a result of the action of sorting mechanisms only the smallest particles are presented to the ingesting surface. The diverticula possess none of the functions of a liver or of a pancreas, but are organs of absorption and of intracellular digestion.

INBREEDING.—In a discussion of inbreeding from the practical breeders' point of view, Mr. A. D. Buchanan Smith (*Eugenics Review*, vol. 18, No. 3) gives many data from the history of Shorthorn cattle and Clydesdale horses. He concludes that Sewall Wright's method of measuring the coefficient of inbreeding is probably best. There has been considerably more inbreeding in Shorthorns than in Clydesdales, but the latter are equally homozygous, probably owing to careful selection. The level of inbreeding must vary with the breed according to the number of undesirable characters still present or latent in the stock and the nature of the selection practised by earlier breeders. Probably the coefficient of inbreeding in Clydesdales will rise much above its present value.

SAMOAN FORAMINIFERA.—J. A. Cushman describes (*Dept. Marine Biol. Carnegie Inst., Washington*, vol. 21, 1924, but only recently received) collections made by the late Dr. A. G. Mayor in Samoa in 1920. The foraminiferal fauna of Polynesia is interesting because living in this region are many forms known elsewhere only fossil. The author expresses his conviction that the shallow-water foraminiferal faunas are as limited in their geographical distribution as many other groups of organisms, and that there are living about oceanic islands many more species of genera such as Quinqueloculina and Spiroloculina than have been suspected. Closer study will, he believes, lead to the recognition of definite faunal areas for Foraminifera such as are known for other groups. The collection at one station in 50 fm. adds many species of especial interest and of rare occurrence. Altogether about 140 species are recorded, 18 of which are described as new, and two new genera are erected.

LONG-LIVED PLANT CELLS.—Dr. D. T. MacDougal points out in the *American Naturalist*, 60, pp. 393-415, 1926, that the living parenchymatous cells of the medulla of the tree cactus, *Carnegiea gigantea*, may continue to grow for more than a century and may still be active until the death of the plant. These old cells behave differently from young cells in the same plant in their reaction to acid or alkaline solution. When immersed in such solutions the young cells become more permeable and have a diminished water-holding capacity. Old cells, on the other hand, have a zone of maximum swelling at such acid reaction as pH 3-3.5 and a secondary maximum between pH 9 and pH 11.

COLLEMBOLA INJURING MANGOLD SEEDLINGS.—In the *Bulletin of Entomological Research*, vol. 17, October 1926, Mr. W. Maldwyn Davies records a significant attack on mangolds by the springtail, *Bourletiella hortensis*. The infestation occurred on one of the fields attached to the Rothamsted Experimental Station, the insects being extremely abundant during the first week of June 1926. Practically 100 per cent. of the seedling mangolds showed leaf damage due to the gnawing propensities of this insect. The nature of the damage was two-fold, for in addition to the actual biting and enlarging of the injured areas, wounds thus caused were kept open and excessive loss of sap ensued. Methods of control were carried out and a contrivance is described by means of which tarred sacking was hung in such a manner that it trailed just above the ridges. As the apparatus was pushed along the Collembola became disturbed by the shadow of the machine and, exercising their characteristic habit of leaping, became trapped in large numbers on the adhesive surface of the tar. This method of control proved so successful that a simple and more permanent type of apparatus attached to a pair of bicycle wheels, easily pushed by a farm hand, was devised for future use.

PERMO-CARBONIFEROUS FAUNA OF JAPAN.—The fauna of the Permo-Carboniferous limestone of Nagato is described by Y. Ozawa (*Jour. Coll. Sci. Imp. Univ. Tokyo*, 45, 6, 1925). It consists mainly of foraminifera and rugose corals, with a few brachiopods and polyzoa. 67 species or varieties of foraminifera are described, of which 51 belong to the Fusulinidæ. The corals belong to the genera Lonsdaleia, Waagenophyllum, Dibunophyllum and Nagatophyllum; one form of Lonsdaleia is identified with a British species, and the Dibunophyllum is regarded as only a variety of a species found in England. In another memoir (*ibid.* 45, 4, 1925) the same author discusses the classification and evolution of the Fusulinidæ.

WORLD WEATHER.—The Royal Meteorological Society has issued a Memoir (vol. i. No. 5) entitled "The Nile Flood and World Weather," by Mr. E. W. Bliss (price to non-fellows, 2*s.* 6*d.*). To establish the relationship it has first been necessary to find a series for the Nile flood. Aswan discharges provide the truest measure of the flood, values of which have been communicated by the Director-General of the Physical Department, Cairo. The values for the four months July to October together are dealt with for the separate years 1869 to 1925. Correlation coefficients are given with pressure, temperature, rain, ice, and wind. Coefficients with pressure give a high negative figure with Cairo, −0·64 for the June to August quarter. The connexion is closest in June to August, but it begins in March to May and persists throughout the following quarters. Rainfall is usually associated with low pressure, but this is scarcely the whole explanation in the present case. After a high Nile flood the North Atlantic circulation is weak, as seen from the coefficients with pressure in Iceland for December to February. Other associations with a good Nile are low equatorial temperatures as shown by Samoa, Batavia, Senegal, and Port-au-Prince. Pressures in the same season are also low, especially in the South Indian Ocean. Like the monsoon, the Nile has closer relations with succeeding than with preceding weather. There is some evidence of a simultaneous connexion with Antarctic conditions.

ELECTRIFICATION OF BALLOON FABRICS.—During the War the risks to airships due to lightning discharges and to their electrification by atmospheric electricity were frequently discussed, but as accurate data were not available, little progress was made in estimating them. We are glad, therefore, that the Aeronautical Research Committee has published a report, No. 1017 (M. 37), by Dr. Guy Barr, on experiments relating to the electrification of balloon fabrics The results prove that spraying the fabric with metal makes the fabric a good conductor but increases its weight by about four ounces per square yard. The surface resistance of the fabric increases if it is crumpled. Fabric 'doped' on the upper surface after having been sprayed on the under surface was satisfactorily conducting after five months' exposure. When the plies of a rubber-proofed two-ply fabric were rapidly separated it was found that the cotton surface left bare became positively charged, and that the rubber attached to the other ply became negatively charged. The experiment was tried of separating the plies of three different rubbered fabrics in a mixture of hydrogen and air, but in no case did any explosion occur. Dr. Barr thinks that this does not prove that ignition cannot take place in any circumstances. So many conditions, however, have to be satisfied that an explosion due to this cause would be a very rare phenomenon, although a considerable electrical effect is produced by separating a heavy rubber proofing from cotton. It is suggested that the graphitisation of the fabric be studied more closely. Further exposure tests should be made and researches carried out to see if the conductivity can be further improved.

THERMAL PROPERTIES OF POTASSIUM AND SOME ALKALI HALIDES.—In order to test the statement of physicists concerning the various electron displacements and dissociations accompanying atomic and molecular energy changes, thermal data calculated from vapour measurements are desirable. On account of the poor agreement between the few existing values, E. F Fiock and W. H. Rodebush have recently determined the vapour pressures of potassium and some alkali halides in an electrically-heated apparatus of nickel. In discussing the results in the *Journal of the American Chemical Society* for October, the authors point out that the most striking feature is the extremely small value of the heats of solution of the solid salt in spite of the large values of the heats of vaporisation and the lattice energies, a fact which is in agreement with Born's theory of lattice energy.

ELECTRIC DISCHARGE THROUGH HELIUM.—In *Scientific Papers of the Institute of Physical and Chemical Research*, Tokyo, No. 69, Dr. T. Takamine describes the results of some experiments on the discharge through helium by two methods: first, the method of exploding wires at high current densities, introduced by Anderson; and secondly, the ordinary condensed discharge in helium at pressures between ½- and 1-atmosphere. In each case some of the lines showed apparent reversal (though not the same lines in the two sets of experiments). Reasons are given for thinking that the appearance is in reality a Stark effect due to the interatomic electric fields, and it is suggested that 'unsymmetrical reversals,' which are commonly met with in spectroscopic work, may sometimes be due to the same cause, and not, as is usually supposed, to absorption.

AN ANCIENT EGYPTIAN COSMETIC.—One of the many interesting objects found by Dr. H. Carter in the tomb of Tut-ankh-Amen at Luxor was a sealed cosmetic jar of calcite. When opened it was found to contain a considerable quantity of cosmetic, consisting of a rather heterogeneous mixture with a decidedly fatty smell. The substance has been carefully examined by A. C. Chapman and H. J. Plenderleith, but unfortunately the results, which appear in the *Journal of the Chemical Society* for October, do not definitely prove the nature of the fats originally employed in its preparation. It seems probable that the cosmetic consisted of about 90 per cent. of a neutral animal fat with about 10 per cent. of some resin or balsam, the latter in the process of time giving rise to the smell of the material, which is one of its most characteristic features.

THE ATOMIC WEIGHT OF SILVER.—The October issue of the *Journal of the Chemical Society* contains an important paper by H. L. Riley and H. B. Baker on the determination of the atomic weight of silver by finding the direct ratio of silver to oxygen in silver oxide, a method which has hitherto failed owing to loss of oxygen on drying the oxide. The product obtained by drying over pure phosphorus pentoxide at ordinary temperatures or in a vacuum at 100° gave a pink chloride with hydrochloric acid, indicating that some very small amount of oxygen was lost, but it was thought, nevertheless, that this loss might be negligible. Samples of pure silver oxide were prepared in an apparatus of special design, but the analyses proved that appreciable quantities of oxygen had been lost, a result contradictory to the preliminary experiments. It was found that the silver oxide was being reduced by small amounts of organic material which passed through the drying tubes. When precautions were taken to exclude organic matter, a product was obtained which gave a perfectly white chloride on precipitation with hydrochloric acid Samples of the pure oxide were decomposed in a silica tube in a current of pure air at 350°-400°, and the silver finally melted in an atmosphere of pure hydrogen. From the loss in weight of the silver oxide and the weight of the residual silver the value of the atomic weight of silver was calculated, the mean value being $107{\cdot}864 \pm 0{\cdot}0013$. This includes, however, a correction for a small amount of water from which it was impossible to free the silver oxide.

MOLECULAR STRUCTURE.—In his recent presidential address to the chemical section of the Australian Association for the Advancement of Science, Prof. James Kenner took as his subject "Some Aspects of the Problem of Molecular Structure." In it he gives a full account of the present position of the theory of valency. He does not confine himself to a discussion of the evidence obtained by purely chemical methods, but gives due place to the results of such other methods of attack as the X-ray investigation of crystals. One of the successes of the modern atomic model was that the electron distribution provided a ready explanation of the formation of many of the simpler molecules, but there is still a long way to go before all the facts known to present-day chemistry are satisfactorily explained. The true nature of the so-called homopolar bond is still unknown. The Werner hypothesis of a uniform attraction round an atom has been very useful in stimulating chemical research and in classifying compounds, but it cannot be said to be entirely consistent with modern views of atomic structure. Recent work suggests that not only the very outermost electrons but also those in the outer sub-groups play an important part in chemical combination, and on such a basis it appears probable that a satisfactory interpretation will eventually emerge. Whatever the final explanation, Prof. Kenner's address should serve a useful purpose in that it gives a broad survey of the existing position and indicates the lines along which progress is being made. Too often the workers in one branch are unfamiliar with the results obtained by other methods, and this address should result in a closer co-ordination of their efforts, the more so as, appended to it, there is a very full list of references to modern literature.

Rectal Alimentation.

THE difficulty of securing adequate nourishment in certain conditions in which the taking of food by mouth is impossible or inadvisable, such as coma or following operations on the gastro-intestinal tract, is well known; the attempt is usually made to supply a certain amount of food and drink by means of nutrient enemata, but there are very few substances which are with certainty absorbed through the mucous membrane of the rectum and large intestine. The knowledge that this part of the bowel in man acts mainly as an absorber of water, and contains none of the digestive enzymes which are found in the upper parts of the gastro-intestinal tract, would suggest that only the ultimate products of digestion of the foodstuffs would stand any chance of being absorbed: such, in fact, appears to be the conclusion to be drawn from many researches on this subject. Dextrose, lævulose, amino-acids, saline solutions, and alcohol are absorbed and thus become available for metabolic processes, but the proof of their actual utilisation has not been so easy to obtain. A recent study by T. M. Carpenter brings forward some new evidence on this question (Carnegie Institution of Washington, Publication No. 369, December 1925).

The experiments were conducted on four healthy medical students; the test substances used were alcohol, dextrose, and lævulose, and their utilisation was studied by observing their absorption when introduced rectally, their excretion in the urine, and their influence upon the respiratory exchange, the pulse rate, and the composition of the urine. The amounts absorbed were obtained by analysing a wash-out enema, which followed the introduction of the nutrient solution: the spirometer or respiration chamber was used for the determination of the respiratory exchange and the pulse rate was recorded by means of a pneumograph placed over the thigh. Among the details to which attention must be directed, so as to ensure the comfort of the subject, are the temperature of the solution and the rate of administration and the total volume given: it was found that the most comfortable posture was the supine, and that the enema should enter the rectum at body temperature, and slowly, preferably by drops: 250 to 500 c.c. can be given in the course of two hours.

The experiments were generally carried out in the afternoon and evening, and the subjects had previously fasted for several hours, but not for the twelve hours usual before an estimation of the 'basal' metabolism. In the majority, one or more preliminary periods were run before the injection was made. The general course of events in a normal subject was studied in a series of control experiments, in which a solution of sodium chloride alone was injected. The changes observed were only slight. The respiratory quotient remained steady, the pulse rate and oxygen consumption fell somewhat, the latter after a slight rise, and the urine, although showing a slightly increased output of fluid, yet had less sodium chloride present: presumably the greater salt excretion in the preliminary period should be related to the intake of this substance in the food. When the experiment continued all night, records of sleep and wakefulness were obtained by the response of the subject to an electrical signal: the pulse rate remained steady, except for periods of wakefulness, and the respiratory quotient, oxygen consumption, and carbon dioxide production showed a tendency to increase slightly. The course of events after the injection of a test substance must be interpreted in the light of those occurring under similar conditions in a control subject at a similar period of the day.

The absorption of alcohol, injected in a 5 to 10 per cent. solution in 0·6 per cent. sodium chloride, was almost complete, in most of the experiments a tota of 25 gm. being given. Signs of alcoholic intoxication could be produced by administration by this route Small amounts of alcohol were excreted in the urine the concentration being of the order of 0·5 per cent and reaching a maximum in about two hours: The amount excreted and the time of the maximum output depended on the quantity of alcohol injected and also on its concentration. Similar results were obtained following the ingestion of alcohol by mouth: but owing to the quicker absorption, a higher maximum excretion was observed. After five or more hours the excretion ceased. If the subject slept during the experiment, more alcohol appeared in the urine suggesting a lessened utilisation It is of interest to note that sometimes the alcohol appeared in the urine in a conjugated condition, distillation following treatment with an inorganic acid yielding slightly higher figures for alcohol than simple distillation alone. The excretion of only small quantities of alcohol after oral ingestion has been confirmed more recently by H. W Southgate (*Biochem. Jour.*, vol. 19, p. 737, 1925) Apart from its presence in the urine, the rectal administration of alcohol led to a marked diuresis, with a decrease in the nitrogen and sodium chloride eliminated.

The effect of alcohol on the general metabolism was shown by the fall in the respiratory quotient, with a rise in the pulse rate and the oxygen consumption When adequate amounts were given, the changes began in about an hour and lasted for six or seven hours. With oral ingestion the respiratory quotient fell still more promptly.

The administration of dextrose or lævulose by the rectal route produced similar effects, except that the respiratory quotient rose, instead of falling, as after the alcohol. Only 60 to 90 per cent. of the dextrose and 50 to 100 per cent. of the lævulose was absorbed in the different experiments; absorption was most rapid in the first two hours. The lævulose solution was the most difficult of all to retain. The changes in the urine were slight in the case of dextrose, there occurring a fall in the nitrogen and sodium chloride output: but this fall was very marked following the injection of lævulose. In both cases the respiratory quotient and the pulse rate increased, with little alteration in the oxygen consumption.

Perhaps the most interesting part of the monograph are the deductions made by the author from the experimental data. He considers that there is sufficient evidence to show that alcohol, dextrose, and lævulose, when introduced rectally, are metabolised by the body. Calculations suggest that alcohol replaces in metabolism all the foodstuffs in the proportions in which they are being utilised at the moment, this replacement may take place to the extent of 50 per cent. By the oxidation of the dextrose absorbed enough carbohydrate would be supplied for the metabolic needs of the body for two to three hours. Lævulose, on the other hand, appears to be mostly retained in the body without oxidation, perhaps as glycogen.

Comparison of the effects of rectal administration with those following oral ingestion showed in a few cases certain discrepancies. Thus alcohol *per os* lowered the respiratory quotient more promptly than after administration by the alternative route, but the peak of the alcohol concentration in the urine was reached in about the same time in either case, so that it may be assumed that the difference is not due to the earlier appearance of an increased concentration in the blood following oral ingestion. Again, lævulose *per os* had a greater effect on the respiratory quotient than when given *per rectum*, whilst with dextrose the reverse appeared to be true, although it was less readily absorbed from the rectum than the former.

The author considers that the differences in the metabolic effects between oral and rectal administration cannot be explained by the absorption of the materials into the systemic venous system alone as distinct from an absorption into the portal system, since the former drains only the extreme lower end of the large bowel. He therefore suggests that the immediate fate of these materials may depend in part upon whether the liver is in an active condition or not. This condition is presupposed following oral ingestion, but if the rectal administration occurs sufficiently long after the previous meal, it may be expected that this organ is in a state of relative quiescence. The idea that the liver may give off to the blood-stream a substance of the nature of an internal secretion has already been envisaged by some experiments of Cannon's on the existence of a substance causing acceleration of the denervated heart, which was only clearly demonstrated in animals digesting meat.

The work suggests lines for future research and at the same time indicates that if resort has to be made to rectal alimentation in a patient, alcohol and dextrose are the substances which should be chosen for this purpose.

The Russian Geographical Society.

WE have received from the Russian State Geographical Society twelve parts of its *Isvestiya*, forming vols. 52-57, for the years 1916–1925. They contain a series of valuable contributions to the geography of the Russian dominions, and British geographers will gladly welcome the renewed activity of that important Society. The word 'Imperial' in the title of the Society was omitted in 1916 and has now been replaced by 'State.' That the conditions of publication in Russia are difficult are indicated by the poverty of the paper, the sparseness and inferior quality of the illustrations and the maps. In these respects the later volumes show a marked improvement, which encourages the hope that the journal will reach its former excellence. The volumes contain many important contributions, but they are rigidly confined to the Russian language, the only exception being that one paper has a title and a short summary in French. If the titles of the papers and the lists of contents were repeated in some western language, the accessibility of its contributions would be much increased. Some of the work has been delayed in publication; thus volume 57, pt. 1 (pp. 3-60), includes papers by Conradi, Kell, and Ghulten on the geological and geographical results of an expedition to Kamchatka in 1908–1910, and a discussion by Prof. Karakash of *Eoanthropus dawsoni* (vol. 52, 1916, pp. 673-714) has been generally overlooked in Great Britain.

Among the papers on physical geography are the discussion by S. C. Bergh (vol. 52, pt. 8, 1916, pp. 579-648) of the origin of loess; many contributions to glacial geography, including a study of the movements of glaciers in the Caucasus by P. Tzirulnikov (vol. 53, 1917, pp. 45-56, 5 pls.), two papers by Belyaev and Besedin (vol. 55, pt. 1, 1919, pp. 1-124) on glaciers in Darvaz from observations during an excursion by the Russian Geographical Society in 1919, and a catalogue by Tronov of the glaciers of the Altai (vol. 57, pt. 2, pp. 107-159). General problems connected with glaciation are discussed by Sobolov (vol. 56, pt. 1, 1924, pp. 101-140, and pt 2, pp. 5-36) on the glacial formation of northern Europe with reference to the geo-morphology of the Russian plain. The evidence from the Caucasus as to the succession of glacial periods is adduced by Renngarten from the Valley of Assa in the northern Caucasus (vol. 57, pt. 2, 1925, pp. 53-106). I. N. Shamkov describes the climate of Abas-Fuman and its value as a health resort.

The papers on European geography are relatively few, but Alyabev (vol. 56, pt. 1, 1924, pp. 5-54) contributes an account of the Kurghalov Peninsula and the south coast of Finland, and their geographical relationship. Yakovlev (vol. 57, pt. 2, 1925, pp 3-22) describes the relief of Leningrad and its effect on the inundations.

Shokalskii in a short paper discusses the acceptance of republics by the north-western Russian States (vol. 56, pt. 1, 1924, pp. 154-161), and A. Petrov discusses the physical geography of the Murmansk area (vol 55, pt. 2, 1924, pp. 3-13)

Studies of the Siberian rivers are given by Saporhnikov and Nitikin, dealing especially with the plant distribution on the lower valley of the Obi (vol. 55, pt. 1, 1923, pp. 135-180); and by Ghromov, who describes his work at the mouth of the Yenisei (vol. 56, pt. 2, 1925, pp 107-118).

Contributions on Russian Turkestan include the papers by Spiridonov on the natural history of parts of the Kizil-Kuma (vol. 56, pt. 2, 1924, pp. 145-173), and Smirnova describes the western parts of the Kirghiz Territories (vol. 55, pt. 2, pp. 103-112); Pavlov describes the North Gobi Desert and a traverse of Mongolia (vol. 57, pt. 1, 1925, pp. 111-168).

Mushketov describes the eastern Ferghana and the Alai (vol. 53, 1917, pp. 83-137, 8 pls.), and also a journey in Narjensk and Kashgar (*ibid.*, pp. 138-166). There are some obituaries, including one of P. O. Rovinskii, dealing especially with his work in Serbia (vol. 52, 1916, pp. 515-542), and an appreciation by Sokolovskii of the geographical work of Philip Avril (vol. 57, pt. 1, 1925, pp. 67-98).

Peat Investigation in Canada.

ABOUT eight years ago a Peat Committee was appointed by the Government of Ontario and the Federal Government of Canada, and was directed to find, if possible, a practical commercial method for converting raw peat into fuel. The Committee considered carefully all the more important processes for winning peat fuel which had been previously proposed, and concluded that the only practical commercial method of winning peat fuel is by excavating, mixing, spreading and forming the raw peat by automatic machines. The peat blocks thus formed and spread are then to be dried in the air. Since this process decreases considerably the number of labourers required per ton of fuel, it is well adapted for countries such as Canada, where the cost of labour is high.

The Committee made a careful and exhaustive examination of the efficiencies of two large-scale excavating and spreading plants. One of these had been devised in Sweden by Anrep, and the other in

Canada by Moore. The two machines were provided with mechanical excavators, which, however, differed in detail, and with field-presses. The conveying of the peat pulp from its excavator to the drying ground was by means of tipping cars on a portable railway in the Anrep method, and by means of an automatic belt-conveyer in that of Moore. As a result of the trials, which are fully described in its final report, the Committee found that the best type of process is one which combines the excavating elements of the Anrep system with the conveying and spreading elements of Moore's.

Incidentally it was found that a shredding machine of the Jeffrey swing-hammer type, used for pulping kelp on the Pacific coast of America, is far more efficient as a macerator than those with knives and screws commonly employed in Europe. Two other conclusions of the Committee deserve the serious attentions of peat experts. The operations of excavating, macerating, forming and spreading can be efficiently performed by automatic machines, but there is no cheap automatic method of collecting dry peat sods from the spreading ground. Furthermore, with the introduction of automatic machines for winning the peat, the overhead charges have increased so much that they now amount to nearly half the total cost of the finished peat fuel.

The report of the Committee merits a careful study, not only because it describes the field results of actual large-scale experiments on the winning of peat fuel, but also because it gives in addition a comprehensive and authoritative account of the recent advances in the peat industry. HUGH RYAN.

University and Educational Intelligence.

BIRMINGHAM.—The following appointments have been made:—Dr. Edmund L. Hirst, to be a lecturer in the Department of Chemistry; Mr. Gordon Manley, to be assistant lecturer in geography; Dr. Oscar Brenner, to be part-time assistant in pathology and bacteriology.

The British Thomson-Houston Co. has presented two A. C. motors for use in the Coal Treatment Laboratory.

The Huxley Lecture is to be delivered by Prof. Elliot Smith on February 1, 1927.

CAMBRIDGE.—D. H. R. Rastall has been elected to a supernumerary fellowship at Christ's College. The following have been elected to represent the scientific faculties on the General Board of the Faculties: Mr. R. H. Fowler, Prof. C. E. Inglis, Dr. T. S. Hele, Mr. T. C. Nicholas.

The Governing Body of Emmanuel College offers to a research student commencing residence at the University in October 1927 a studentship of the annual value of 150*l*., tenable at Emmanuel College for two years. The studentship will be awarded in July, and applications should be sent so as to reach the Master of Emmanuel (The Master's Lodge, Emmanuel College, Cambridge, England) not later than June 30. The award will be made on the evidence submitted by the candidates, which should include a statement of the proposed course of research, a brief account of the candidate's career up to the date of the application, and evidence of general ability and of special fitness for the proposed course of research.

LIVERPOOL.—Dr. W. S. Patton, lecturer on entomology in the University of Edinburgh, has been appointed to the Dutton Memorial chair of entomology at Liverpool as from January 1 next. Dr. Patton graduated in medicine at Edinburgh in 1901 and later studied in the University of Marburg. He joined the Indian Medical Service in 1902, from which he retired with the rank of major in 1921. During the War he was entomologist to the Mesopotamian Expeditionary Force. He has acted as Director to the King Institute of Preventive Medicine in Madras and as Director of the Pasteur Institute of Southern India. He has recently been engaged in investigations in China, and has had charge of the Kala-Azar Commission of the Royal Society.

Prof. H. J. W. Hetherington, professor of moral philosophy in the University of Glasgow, has been appointed Vice-Chancellor of the University of Liverpool in succession to the late Dr. J. G. Adami. Prof. Hetherington was educated at Dollar Academy and the University of Glasgow, in which he distinguished himself in the Departments of Mental Philosophy, Economics, and Classics. From 1910 until 1914 he held a lectureship in moral philosophy in Glasgow and became a member of Merton College, Oxford. In 1914 he was appointed lecturer in philosophy in the University of Sheffield, and a year later became professor of logic and philosophy in University College, Cardiff. In 1920 he became Principal and professor of philosophy of University College, Exeter, in which positions he distinguished himself as an administrator. In 1924 he relinquished his post in Exeter to take the chair of moral philosophy in Glasgow University. He is thirty-eight years of age. Prof. Hetherington is the author of "International Labour Legislation" and has published, in conjunction with Prof. J. H. Muirhead, a study in social philosophy entitled "Social Purpose." He will assume the office of Vice-Chancellor at the beginning of the session 1927–28.

APPLICATIONS are invited by the Royal Society for the appointment of a Foulerton Research Studentship, value 700*l*. per annum. The duties of the student will be to conduct researches in medicine or the contributory sciences under the supervision and control of the management committee. The studentship will be tenable for three years, but may be renewed from year to year up to six years. Members of either sex are equally eligible, but must be of British nationality. Applications must reach the Royal Society, Burlington House, Piccadilly, W. 1, not later than March 1 next.

THE annual meeting of the Geographical Association will be held on January 6-8 at the London School of Economics, Houghton Street, Aldwych, W.C.2, under the presidency of Sir Charles Close, formerly Director-General of the Ordnance Survey. The programme includes a discussion on January 6 for university teachers of geography on research in geography (opened by Sir Henry Lyons), and an address by Mr. J. Fairgrieve to primary school teachers, and a visit on January 7 to the Science Museum, South Kensington, with an address by Prof. H. H. Turner on solar eclipses. There will also be four concurrent discussions on the morning of January 7, on geography in advanced courses, on broadcasting and nature-study respectively in geography, and on school journeys. Sir Charles Close will deliver his presidential address, "Population and Migration," on January 7, and later in the day Col. E. M. Jack, the present Director-General of the Ordnance Survey, will describe the work of his department. The annual dinner of the Association will be held on January 7, and on January 8 a visit to the geography room of the William Ellis School is being arranged. Prof. L. P. Abercombie of Liverpool is organising a visit on January 8-10 to see the changes taking place in east Kent. The honorary secretary of the Association is Prof. H. J. Fleure, Geographical Association, Marine Terrace, Aberystwyth.

Contemporary Birthdays.

December 12, 1838.	Prof. W. C. Unwin, F.R.S.
December 12, 1866.	Prof. E. W. MacBride, F.R.S.
December 12, 1855.	Mr Arthur William Clayden.
December 13, 1861.	Prof. A. G. Perkin, F.R.S.
December 15, 1869.	Sir John F. C. Snell, G.B.E.
December 16, 1884.	Prof. John W. Bews.
December 16, 1859.	Prof. Douglas H. Campbell
December 16, 1854.	Prof. John T. Cash, F.R.S.

Prof. UNWIN celebrates his eighty-eighth birthday on Sunday, and very hearty congratulations are accorded to this distinguished veteran of the engineering world. Educated at the City of London School, he began his technical career as a pupil in the firm of William Fairbairn, Manchester. For twenty years he taught the principles of engineering at the Central Technical College, City and Guilds of London Institute. Prof. Unwin is a past president of the Institutions of Civil Engineers and Mechanical Engineers.

Prof. MACBRIDE, the distinguished zoologist, who occupies the chair of zoology in the Imperial College of Science and Technology, South Kensington, was born at Belfast and educated there at Queen's College, and at St. John's College, Cambridge. From 1897 until 1909 he was Strathcona professor of zoology in McGill University, Montreal. A teacher of distinction, Prof. MacBride has made noteworthy contributions to invertebrate embryology. In 1924 he published his "Introduction to the Study of Heredity."

Mr CLAYDEN was born at Boston, Lincolnshire, and educated at University College School, from whence he graduated at Christ's College, Cambridge. From 1894 until 1920 he was principal of University College, Exeter. Mr Clayden has contributed much of sterling value to meteorological photography.

Prof. A. G. PERKIN, who, it will be recalled, retired recently from the chair of colour chemistry and dyeing in the University of Leeds, was born at Sudbury. He was educated at the City of London School and Royal College of Science. In 1924 the Royal Society awarded him its Davy medal for researches on the structure of natural colouring matters.

Sir JOHN SNELL was born at Saltash, Cornwall, and educated at Plymouth Grammar School and King's College, London. A past president of the Institution of Electrical Engineers, he is a member of the Advisory Council, Department of Scientific and Industrial Research, and the General Board, National Physical Laboratory. Sir John's advice and guidance are sought frequently in parliamentary projects concerning the technical industries.

Prof. BEWS, born at Kirkwall, Orkney, graduated at the University of Edinburgh. Assistant professor of botany there (1908–10), he left to take up the chair of botany in University College, Natal. In 1924 he published "Plant Forms and their Evolution in South Africa."

Prof. D. H. CAMPBELL, botanist, was born at Detroit, U.S.A. After graduation at the University of Michigan, he studied at Bonn, Tübingen, and Berlin. Professor of botany at Indiana University from 1888 until 1891, he was then elected to a similar chair at Stanford University, California. Prof. Campbell is a foreign member of the Linnean Society of London and a fellow of the Royal Society of Edinburgh. He is the author of "Plant Life and Evolution" (1911) and of many papers on systematic botany.

Prof. CASH, a graduate of the University of Edinburgh, is Emeritus Regius professor of materia medica in the University of Aberdeen.

Societies and Academies.

LONDON.

Royal Society, December 2.—**T. M. Lowry** and **W. R. C. Coode-Adams**: Optical rotatory dispersion (Pt. 3). The rotatory dispersion of quartz in the infra-red, visible, and ultra-violet regions. Measurements of optical rotatory power of quartz were begun in 1908 with the view of testing, in the most drastic way possible, methods that were being developed for studying rotatory dispersion in organic compounds. Data are now given for the rotatory power at 20° C. of a column of quartz, 496·4735 mm. in length, over a range of wave-lengths from 25,170 Å.U. to 2263 Å.U. Observed rotations range from 450° to 101,332°, and rotations per mm. from 0·906° to 202·328°/mm. The latter can be expressed, over the entire range of wave-lengths, by the formula—

$$\alpha = \frac{9{\cdot}5639}{\lambda^2 - 0{\cdot}0127943} - \frac{2{\cdot}3113}{\lambda^2 - 0{\cdot}000974} - 0{\cdot}1905$$

This formula postulates the existence of bands of selective absorption at 1130 Å.U. and 310 Å.U. The influence of infra-red bands is covered by the small constant $-0{\cdot}1905$.

O. W. Richardson: Structure in the secondary hydrogen spectrum (v). Fulcher's red bands as extended by various authors form a sequence of bands with the respective vibration transitions 0 → 0, 1 → 1, 2 → 2, 3 → 3, 4 → 4, and 5 → 5. The green bands belong to the same group and have the vibration transitions 1 → 0, 2 → 1, 3 → 2, 4 → 3, and 5 → 4. Associated with these are five bands in the infra-red with transitions 0 → 1, 1 → 2, 2 → 3, 3 → 4, and 4 → 5, and four in the blue-green with transitions 2 → 0, 3 → 1, 4 → 2, and 5 → 3. The blue bands arranged by Dieke form a sequence in another group and have the transitions 0 → 0, 1 → 1, 2 → 2, 3 → 3, and 4 → 4. Belonging to this group are three other sequences with transitions 1 up, 1 down, and 2 down respectively. There are also at least three less well-developed groups in the violet side of these. The Q (1) lines of the bands with 0 → 0 vibration transitions are given by the Rydberg-Ritz formula

$$\nu = A - \frac{R}{(m - 0{\cdot}056704 - 0{\cdot}06080/m^2)^2},$$

where $A = 29330{\cdot}305$, $R = 109678{\cdot}3$, and $m = 3, 4, 5, 6, 7, 8$. The value of A is close to that of the second member when $m = 2$. It follows that the various groups of bands are associated with electron transitions 3 → 2, 4 → 2, 5 → 2, etc. The lines of the Q branches are connected together by a combination rule which extends not only within each group but also from each group to the others.

R. H. Fowler: General forms of statistical mechanics, with special reference to the new quantum mechanics. This paper discusses a very general form of statistical mechanics which includes as special cases the classical form, the form of Bose and Einstein, and of Fermi and Dirac. It is shown generally that assemblies of many independent systems are always thermodynamic systems. The correct form for material particles obeying the laws of quantum mechanics is then discussed, and the arguments in favour of the form of Fermi and Dirac summarised. The applications of this form are then greatly extended. Previously it had been applied only to structureless mass-points; it is here shown how to treat assemblies as general as any handled in the classical form. Problems of distribution in space according to the new mechanics are also briefly treated.

R. H. Fowler and **E. K. Rideal**: On the rate of maximum activation by collision for the complex molecules, with applications to velocities of gas particles. New formulæ are used to compute the maximum rate of activation by collision and applied to the dissociation of nitrogen pentoxide. The maximum possible rate of activation by collision is 100 times greater than the observed rate of dissociation at the lowest pressures hitherto investigated. The maximum possible rate of dissociation of bromine molecules by collision and the rate of formation of hydrobromic acid are of the same order. The rate of dissociation need not be 10^5-10^6 times smaller, as claimed by Polanyi.

H. **Dingle**: The spectrum of fluorine (F I). The spectrum of neutral fluorine (F I) has been examined by means of discharges through silicon tetrafluoride, and lists of established and doubtful lines have been tabulated. It contains doublet and quartet systems of terms. The suggested arrangement is consistent with Carragan's observations of the Zeeman effect for fluorine. Relative term values have been deduced for each system, and an ionisation potential of about 17 volts suggested. The discussion suggests that lines of F I should appear with maximum intensity at or near Ao in the Harvard sequence.

Eighteen papers were read in title only.

MANCHESTER.

Literary and Philosophical Society, November 2.—H. B. **Dixon** and W. F. **Higgins**: The burning of gases in nitrous oxide. A small jet of hydrogen burning in air is almost invisible and its light is inappreciable: if nitrous oxide, instead of air, is made to feed the flame, the increase in the size and luminosity of the flames is remarkable The jet of issuing gas is surrounded by a luminous apricot-coloured zone, and outside this is a thick sheath of greenish-grey colour. The luminous zone appears to give a continuous spectrum, and this is confirmed by a spectrogram taken with a 24 hours' exposure Hydrocarbon gases burning in nitrous oxide show an intensely bright centre surrounded by a luminous apricot zone, and round all a wide-stretching green-grey envelope The propylene and acetylene flames deposit a sheath of carbon round their luminous cores. All the gases tested in the 'concentric-tube' apparatus have ignition-points in nitrous oxide lower than those in oxygen or air. They all exhibit a lowering of nitrous-point above and below the *crucial pressure*, just as in oxygen or in air.—R. W. **James**: The intensity of reflexion of X-ray from crystals at low temperatures. The temperature coefficient of X-ray reflection from crystals of rock-salt over a range of temperatures from 290° Abs. to 85° Abs. has been measured. The crystal is suspended just above the surface of liquid air contained in a Dewar flask having specially thin walls made of boro-silicate glass. With molybdenum $K\alpha$ the absorption in the glass is only about 30 per cent. The ratios of the intensities of reflection at 85° Abs. to that at 290° Abs are 1·22, 1·61, 2·36, 3·39, for the 2nd, 3rd, 4th, and 5th order reflections respectively, from the cube face of the crystal. This is in accord with Debye's theory. At higher temperatures the intensity decreases too rapidly According to recent work by Waller the value of the exponent should be double that calculated by Debye At low temperatures the present experiments point to the substantial correctness of Waller's formula.

November 16.—R **Robinson**: Some recent advances in organic chemistry. In the aliphatic group, special interest attaches to the work of Dudley, Rosenheim, and Starling on the tetra-acid base, spermine, which has been isolated and proved by synthesis to possess the formula—

$$NH_2(CH_2)_3NH(CH_2)_4NH(CH_2)_3NH_2.$$

In the alicyclic group, Ruzicka, after doing much to clear up the chemistry of the sesquiterpenes, has made the astonishing discovery of the stability of large rings of carbon atoms The clue was furnished by the study of the ketone, civetone, from certain glands of the civet cat. This substance was proved to be cycloheptadecenone. In the aromatic groups Harington has studied the active constituent of the thyroid gland and shown it to be the tetra-iodo derivative of a compound termed deiodothyroxin. The latter contains a diphenyl ether group, is related to tyrosine and has been synthesised. Turning to the heterocyclic groups, H. Fischer's recent announcement of the transformation of cryptopyrrole into aetioporphyrin marks a great advance in our knowledge of chlorophyll and of the blood pigment. For the first time the synthetical method affords evidence of the arrangement of the four pyrrole nuclei in the molecule. The most striking feature of recent organic chemical theory is the increasing use which is made of conceptions based on the electronic theory of valency. Thus, it can be shown theoretically that electrophile groups, those which attract electrons and, for example, actually positively charged centres, have a *m*-directive tendency. On the other hand, groups which are less electrophile than hydrogen is, have an *o-p*-directive tendency.

PARIS.

Academy of Sciences, November 8.—Ch. **Lallemand**: A world-wide scheme for measurements of longitude. The scheme starts with the determination of the differences of longitude between three fundamental points, nearly on the same parallel, and about 120° apart. For these points three permanent observatories were chosen (Algiers, Shanghai, San Diego), and these are to be connected by secondary polygons. Full use is made of radio telegraphy, associated with the most perfect methods of astronomical observation available. Wherever possible, self-recording methods are utilised.—H. **Dauvillé**: Some observations on the Cretaceous strata to the south of Paris.—R. Jarry **Desloges**: The changes observed in the planet Mars during the apposition of 1926. A list of changes from the configurations seen in 1924.—J. **Schokalsky**: The expedition of the Russian Geographical Society in Mongolia (1924–1926).—S **Drzewiecki**: A new representation of a gas Application to the barometric pressure. Starting with a simple deduction from the kinetic theory of gases, a new formula for the variation of barometric pressure with altitude is deduced. This formula contains a series in ascending powers of *g*, and if all terms of this series except the first be neglected, it reduces to the ordinary Laplace formula.—W. **Arkadiew**: The oscillations and resonance of elementary magnets.—H. **Volkringer**: The continuous spectrum of mercury The continuous spectrum of mercury vapour under oscillating discharge, studied in a tube without electrodes, was of maximum intensity at about 240° C (vapour pressure 35 mm.). The distribution of energy in the spectrum was determined by comparison with the energy emitted by a black body at 1520° C. The curve given shows a maximum in the neighbourhood of $\lambda = 0{\cdot}512\mu$ and is nearly symmetrical about this point —René **Dubrisay**: The action of heat on the superficial properties of kaolin. Kaolin was heated to 250° C, 550°-600° C., and 950°-1000° C. The unheated sample and the three heated samples were compared with respect to their adsorption of iodine and of methylene blue, the heat developed on moistening with water and ammonia solution, and apparent volume after shaking up with water and ammonia solution. The comparative results of these experiments are given in tabular form.

—**Pierre Jolibois**, **Henri Lefebvre**, and **Pierre Montagne**: Comparison between the effects of the electric spark and of thermal dissociation.—**H. Forestier** and **G. Chaudron**: The ferromagnetic characters of stable iron sesquioxide.—**Jean Cournót** and **Jean Bary**: Electrolytic plating of aluminium and light alloys, their adherence and resistance to corrosion by sea water. Aluminium and duralumin were used in these experiments. The deposited metals were cadmium, cobalt, and chromium (all on a copper film), also cadmium directly on duralumin. Detailed accounts of cleaning methods and depositing baths are given. As regards resistance to sea water, copper-chromium deposited on aluminium gave the best results.—**A. Sanfourche**: The cementation of iron by silicon chloride.—**C. Marie** and **J. Bertheloot**: Two causes of error in the electrolytic determination of nickel in the presence of iron. The precipitated oxide of iron retains some nickel and the deposited nickel contains some iron. These errors may sometimes compensate each other. The first error may be prevented by the addition of magnesium sulphate, the second by using a diaphragm of filter paper round the cathode.—**Georges Dubois**: Geological study of the Flemish coast in the neighbourhood of Gravelines.—**P. Russo**: The presence of a large volcanic region in the lower plain of Moulouya (Northern Morocco).—**Const. A. Ktėnas**: The evolution of the volcano of Kamenis (Santorin) in 1926.—**Louis Besson**: Relation between the temperatures of certain months in the year. Taking the mean monthly temperatures at Paris for 123 years, and plotting the figures for July and April against the date, it is seen that there is a remarkable similitude between the two curves; if one curve is displaced, seven years the two curves are almost parallel.—**J. Magrou**: *Bacterium tumefaciens* in the tissues of plant cancers. The observations described, which agree with those of Robinson and Walkden and of Pinoy, suggest that the agent of cancer in plants acts at a distance, by a mechanism which remains to be explained, on the cells in which it is causing multiplication.—**Stefan Jellinek**: A biological sign marking the return of spontaneous respiration in cases of apparent death. The first sign of restoration of breathing is a swallowing movement of the larynx and lips.—**Alphonse Labbé**: Herouardia, a new genus of copepod, intermediate between the Harpacticidæ and the Cyclopidæ.—**A. Dorier**: The commensalism of the larva of *Dactylocladius brevipalpis*.—**Auguste Lumière** and **Mme. Montoloy**: The formation of abscesses of fixation.

Official Publications Received.

BRITISH AND COLONIAL.

Ministry of Finance, Egypt: Survey of Egypt, Geological Survey. The Geography and Geology of the District between Gebel 'Atâqa and El-Galâla El-Bahariya (Gulf of Suez). By Dr. H. Sadek. (Survey of Egypt Paper No. 40.) Pp. viii+120+6 plates. (Cairo: Government Publications Office.) 10 P.T.

Proceedings of the Isle of Wight Natural History Society for 1925. Vol. 1, Part 6. Pp. cccxxii-cccxviii+319-403. (Newport, I.W.: The County Press.) 3s.

Diary of Societies.

SATURDAY, DECEMBER 11.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South-Western District Meeting) (at Vestry Hall, Dawlish), at 2.15.—S. F. C. Church: Twenty Years in an Urban District.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Associates' and Students' Sections) (jointly with Graduate Sections of North-East Coast Institution of Engineers and Shipbuilders, and Institution of Electrical Engineers) (at Neville Hall, Newcastle-upon-Tyne), at 3.—Joint Discussion on The Production and Transport of Coal by Machinery.

MINING INSTITUTE OF SCOTLAND (at Royal Technical College, Glasgow), at 3.—A. Kyle: Mineral Boring.—Discussions on the following:—Coal-Cutting by Machinery and Conveyors in Scottish Mines, G. L. Kerr.—The Problem of In-bye Transport, D. C. Gemmell.—Miner's Nystagmus, Dr. F. Fergus.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. C. Rootham: Henry Purcell and his Contemporaries (1).

PHYSIOLOGICAL SOCIETY (at London Hospital Medical College), at 3.30.—Demonstrations—A Simple Colorimeter Lamp, H. D. Kay.—An Easily-constructed Ultrafilter, R. S. Aitken and H. D. Kay.—A Method of Collecting 'Alveolar Air' during Exercise, A. E. Clark-Kennedy and T. Owen.—The Fractional Analysis of an Expired Breath, R. S. Aitken and A. E. Clark-Kennedy.—Apparatus for Measuring the Osmotic Pressure of Proteins at Constant Hydrogen-Ion Concentration, J. R. Marrack.—Dr. W. A. M. Smart: Some Nomograms of Physiological Interest.—Prof. H. E. Roaf: (a) Apparatus for Measuring the Influence of Intensity of Light on Discrimination of Wave-lengths; (b) Effect of Exposure of the Eye to a Coloured Light on its Sensitivity to Various Regions of the Spectrum; (c) Apparatus for Measuring the After Effects of Exposure of the Eye to any Region of the Spectrum.—S. Wright: A Simple Respiratory Apparatus for Man or Animals.—D. T. Barry: Experimental Lesions of Mitral and Tricuspid Valves.—E. D. Adrian and R. Eckhard: The Time Relations and Frequency of Impulses in the Optic Nerve.—J. T. Cunningham: The Function of the Scrotum.—H. A. Harris: The Growth of the Long Bones in Health and Disease; its Relation to Vitamines and Tissue-Culture.—Dr. F. W. Edridge-Green: The White Equation and its Relation to the Theory of Colour Vision.—F. R. Curtis, A. A. Moncrieff, and S. Wright: On a Supposed Pressor Substance in the Blood of Patients with Hypertension.—I. de Burgh Daly: Effect of a Negative Pressure on the Heart-Lung Preparation.—K. Furusawa: A Muscle Twitch Lasting for Hours.—D. T. Barry and J. Freud: Toxæmia from Liver Grafting.—Prof. H. S. Raper: Indole Derivatives from Tyrosine.—F. Campbell Smith: The Ultra-violet Absorption Spectra of Centrospinal Fluids (Preliminary Communication).

BRITISH PSYCHOLOGICAL SOCIETY (Annual General Meeting) (at University College), at 3.30.—J. C. Flugel: Practice, Fatigue, and Oscillation.

INSTITUTE OF BRITISH FOUNDRYMEN (Newcastle and District Branch) (at Neville Hall, Newcastle-upon-Tyne), at 6.15.—W. J. Molineux: The Manufacture of Iron Castings for Petrol Engines.

INSTITUTE OF BRITISH FOUNDRYMEN (Birmingham, Coventry, and West Midlands Branch) (at Engineers' Club, Birmingham), at 6.30.—W. West: Oil, Sand, and Motor Castings.

HULL ASSOCIATION OF ENGINEERS (at Hull Technical College), at 7.15.—Prof. F. C. Lea: Hydro-Electrical Developments.

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at Manchester).—R. S. Horsfall: Modern Industrial Chemistry.

MONDAY, DECEMBER 13.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.—Sir Henry Lyons: Ancient Survey Instruments.

SOCIETY OF ENGINEERS (at Geological Society), at 5.45.—Prof. F. H. Hummel: The Economic Proportions, and the Stresses in a Solid Masonry Dam or Buttress, subjected to Water Pressure acting on an Inclined Face.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section) (at Institution of Mechanical Engineers), at 7.—H. H. Lewis: Payment by Results.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Section) (at Liverpool University), at 7.—H. W. Edmundson and G. B. Robertson: The Making of a Radio Valve.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Circle) (at Armstrong College, Newcastle-upon-Tyne), at 7.—J. R. Beard and T. G. N. Haldane: The Design of City Distribution Systems, and the Problem of Standardisation.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section, London) (jointly with Student Sections of the Institutions of Civil and Electrical Engineers), at 7.—H. H. Lewis: Payment by Results.

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—Protection Coating of Metals:—C. H. Faris: Færoolising.—N. C. Marples: Colorising.—E. A. Ollard: Chromium Plating.

RAILWAY CLUB, at 7.30.—W. H. R. Dawson: The Underground Railway.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—G. Drysdale: The Work of Leonard Stokes.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—J. Anderson: The Knower and the Known.

INSTITUTE OF CHEMISTRY (Leeds Area Section).—F. Scholefield: Registration of Chemists.

TUESDAY, DECEMBER 14.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Sir William Bragg: The Imperfect Crystallisation of Common Things (4).

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—Dr. W. R. Ormandy, E. C. Craven, Prof. I. M. Heilbron, and H. J. Channon: A Contribution to the Study of the Origin of Petroleum. The Berginisation of Fish Liver Oils and Other Bodies.

INSTITUTION OF CIVIL ENGINEERS, at 6.—G. Ellson: The Remodelling of Charing Cross and Cannon Street Stations.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—Presidential Address.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—W. B. Ferguson: A Modified F.R.B. Photometer Working with Constant Illumination of Field.—F. J. Tritton: The Application of Copper Salts in the Carbro Process.—A. B. Crow: A New Camera for Colour Photography.

Institute of British Foundrymen (Lancashire Branch, Burnley Section) (at Burnley Municipal College), at 7.15.—Discussion.

Society of Chemical Industry (Newcastle-on-Tyne Section) (at Armstrong College, Newcastle-on-Tyne), at 7.30.—L. H. Sensicle: The Future of High Temperature Carbonisation.

Institution of Electrical Engineers (Scottish Centre) (at Royal Technical College, Glasgow), at 7.30.—J. R. Beard and T. G. N. Haldane: The Design of City Distribution Systems, and the Problem of Standardisation.

Institution of Automobile Engineers (Coventry Centre) (at Parkside, Coventry), at 7.30.—G. Rushton: The L.G.O.C. Methods of Repairing Motor Buses.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch) (at Middlesbrough), at 7.30.—W. J. Williams: Technical Education.

Quekett Microscopical Club, at 7.30.—Miss A. Lorrain Smith: Some Aspects of Lichens in Nature and in Art.

Pharmaceutical Society, at 8.—F. H. Carr: The Vitamins in their Relation to Pharmacy.

Royal Anthropological Institute, at 8.30.—Capt. G. Pitt-Rivers: The Effect on Native Races of Contact with European Culture, followed by a discussion by the Hon. W. Ormsby-Gore, Major A. G. Church, Major H. Vischer, and others.

Royal Society of Medicine (Psychiatry Section), at 8.30.—Dr. W. Aldren Turner: Some Observations upon Epilepsy (Presidential Address).

WEDNESDAY, December 15.

Society of Glass Technology (at University College), at 2.30.—J. F. Hyslop, R. Gumm, and H. Biggs: Some Corrosion and Erosion Phenomena and their Bearing on the Macrostructure of Refractories.—J. F. Hyslop and H. P. Rooksby: A Note on the X-Ray Patterns of Mullite and Sillimanite.—Prof. W. E. S. Turner: Further Note on Sillimanite as a Glass Works Refractory.—V. H. Stott: The Viscous Properties of Glass.—Prof. W. E. S. Turner: The Effect of Cullet on the Melting of Glass.—Dr. S. English: The Design of Parison Moulds.

Royal Meteorological Society, at 5.—N. K. Johnson: Some Meteorological Observations made at Sea.—N. K. Johnson and E. L. Davies: Some Measurements of the Surface Temperatures in Various Kinds of Soil.—Dr. A. N. Puri: Investigation on the Behaviour of Hair Hygrometers.

Geological Society of London, at 5.30.—J. H. Davies and Dr. A. E. Trueman: A Revision of the Non-Marine Lamellibranchs of the Coal Measures, and a Discussion of their Zonal Sequences.—Major L. M. Davies: The Ranikot Beds of Thal (North-West Frontier Provinces of India).

Newcomen Society for the Study of the History of Engineering and Technology (at 17 Fleet Street), at 5.30.—J. G. A. Rhodin: Christofer Polhem, 'The Archimedes of the North.'—A. Waarland: Mårten Triewald and the First Steam Engine in Sweden.

Institution of Civil Engineers (Students' Meeting), at 6.30.—J. G. Kimber: Some Applications and Advantages of Town Gas.

Institution of Automobile Engineers (Manchester Centre) (at Engineers' Club, Manchester), at 7.—F. Randle: Radiator Design.

Society of Chemical Industry (Glasgow Section) (at 39 Elmbank Crescent, Glasgow), at 7.—Dr. E. W. Smith: Some Technical Aspects of the Fuel Problem.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Newcastle-upon-Tyne), at 7.15.—L. P. Tappin: Some Problems of the Locomotive.

Institution of Electrical Engineers (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.

Merseyside Aquarium Society (at 1 Falkland Road, Egremont), at 7.30.—R. J. Daniel: Marine Fishes and their Food.

Society of Technical Engineers (London Area) (at 102 Belgrave Road), at 7.30.—The Present Status and Position of Technical Engineers in Russia (Address).

Royal Society of Arts, at 8.—W. J. U. Woolcock: Some Aspects of the Chemical Industry.

C.B.C. Society for Constructive Birth Control and Racial Progress (at Essex Hall, Strand), at 8.—Lieut.-Col. Sir John Ramsay: Birth Control as an Official and Administrative Question.

Eugenics Society (at London University Union, Malet Street), at 8.—Dr. C. V. Drysdale and others: Discussion on The Common Sense of Heredity: Natural Selection Reversed, Results in Reversal of Evolution.

Folk-Lore Society (at University College), at 8.—C. Tabor: The Folk-lore of Dancing.

Royal Microscopical Society, at 8.—C. Beck: A Method of Testing Zonal Aberration.—S. Hirst: Note on the Development of *Allothrombium fuliginosum* Hermann.—Dr. A. Kefalas: A Method of Staining Sections in Acetone.—Capt. J. Ramsbottom and E. H. Ellis: Seedling Structure of Cultivated Orchids.

Electroplaters' and Depositors' Technical Society (at Northampton Polytechnic Institute), at 8.15.—A. W. Hothersall: Acidity of certain Plating Solutions.

British Psychological Society (Medical Section) (at Royal Society of Medicine), at 8.30.—Dr. B. Hart: The Dissociation of Conception (Chairman's Address).

Merseyside Aquarium Society (at Egremont, Cheshire).—R. J. Daniel: Marine Fishes and their Food.

THURSDAY, December 16.

Royal Institution of Great Britain, at 5.15.—Sir Squire Sprigge: Medical Literature in relation to Journalism.

Child-Study Society (at Royal Sanitary Institute), at 6.—Dr. J. H. Jagger: Criticism of the Infant School.

Institution of Electrical Engineers, at 6.—Col. E. Mercier: Notes on the 60,000-Volt Underground Network of the Union d'Electricité.

Institute of Metals (Birmingham Local Section) (at Engineers' Club, Birmingham), at 7.—Dr. W. Rosenhain: Hardening.

Chemical Society, at 8.—E. J. B. Willey and Dr. E. K. Rideal: On Active Nitrogen. Part I. The Heat of Formation and Nature of Active Nitrogen.—Dr. E. K. Rideal and W. M. Wright: Low Temperature Oxidation at Charcoal Surfaces. Part III. The Behaviour of Blood Charcoal and the Influence of Temperature on the Reaction Rate.—S. G. Clarke, J. Kenyon, and H. Phillips: Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXXI. The Resolution of a Sulphilimine into its Optically Active Forms.

Royal Aeronautical Society.—Wing-Comdr. C. D. Breese: The Training of Aircraft Apprentices.

Institution of Mechanical Engineers (Birmingham Branch) (at Birmingham).—Prof. E. G. Coker: Elasticity and Plasticity (Thomas Hawksley Lecture).

Institution of Mechanical Engineers (Manchester Branch) (at Manchester).—T. A. F. Stone: Electric Locomotives: A Method of Classifying, Analysing, and Comparing their Characteristics.

Institution of Mechanical Engineers (Yorkshire Branch) (at Leeds).—J. H. Barker: Chairman's Address.

Institution of Mining and Metallurgy (at Geological Society).

FRIDAY, December 17.

Society of Chemical Industry (Liverpool Section, jointly with Fuel Section) (at Liverpool), at 6.—H. P. Lupton: Gas Undertakings and the Fuel Problem.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.—Questions and Problems.

Photomicrographic Society (at 4 Fetter Lane), at 7.—Members' Evening.

Society of Chemical Industry (Chemical Engineering Group, jointly with Birmingham Section) (at Birmingham University), at 7.15.—Prof. J. W. Hinchley: Measurement of Temperature in Technical Practice.

Junior Institution of Engineers, at 7.30.—H. D. Glover: Progress Methods employed in a Large Mass Production Motor Works.

Institute of Metals (Sheffield Local Section) (at Sheffield University), at 7.30.—J. E. Hurst: The Influence of Sulphur in Cast Iron.

Royal Society of Medicine (Electro-Therapeutics and Surgery Sections), at 8.30.—Dr. E. P. Cumberbatch (Electro-Therapeutics) and F. J. Steward (Surgery): Discussion on Diathermy.

Society of Dyers and Colourists (Manchester Section) (at Manchester).—H. L. Hockney and C. W. Bancroft: Cloth Dyeing suitable for Rubber Proofing.

Manchester Literary and Philosophical Society (Chemical Section) (at Manchester).

West of Scotland Iron and Steel Institute (at Royal Technical College, Glasgow).—J. E. G. Primrose: Rod Rolling and Wire Drawing.

SATURDAY, December 18.

North of England Institute of Mining and Mechanical Engineers, at 2.30.

Royal Institution of Great Britain, at 3.—Dr. C. Rootham: Henry Purcell and his Contemporaries (2).

PUBLIC LECTURES.

SATURDAY, December 11.

Horniman Museum (Forest Hill), at 3.30.—M. A. Phillips: The Nursery Life of Animals.

SUNDAY, December 12.

Guildhouse (Eccleston Square), at 3.30.—Viscount Grey: The National Genius of England.

MONDAY, December 13.

Royal Sanitary Institute, at 5.—Dr. W. A. Robson: Legal Conceptions of Public Health (Chadwick Lecture).

TUESDAY, December 14.

Royal Institute of British Architects, at 7.30.—W. G. Newton: The Wealth of England.

Swedenborg Hall (Hart Street, W.C.1), at 8.—Rev. C. A. Hall: The Philosophy and Theology of Swedenborg.

WEDNESDAY, December 15.

University College, at 5.30.—Prof. A. E. Richardson: Public Library Architecture.

SUNDAY, December 19.

Guildhouse (Eccleston Square), at 3.30.—Miss Maude Royden: The Debt of Theology to Science.

SATURDAY, DECEMBER 18, 1926.

The New Physics.

SIR JOSEPH THOMSON is being entertained to dinner at Cambridge to-day on the attainment of his seventieth birthday. The event is one in which all who are concerned with scientific progress would desire to be associated in congratulatory expression, though only a limited number of friends are participating in the actual celebration. We are therefore devoting the main part of this week's issue of NATURE, as well as the whole of the special Supplement, to articles on the Cavendish Laboratory and its directors, with particular reference to Sir Joseph Thomson's work and influence. It would of course have been easy to obtain hundreds of appreciative messages for publication on this occasion, but in inviting such expressions of congratulation, we limited ourselves to some distinguished men of science abroad who have carried on research in the Cavendish Laboratory or have devoted themselves particularly to investigations along lines which started there. We are proud of the opportunity of publishing the tributes of affection and esteem received in response to our invitation, and we are sure that they represent the feelings of the whole scientific world.

When, in 1879, the late Sir William Crookes showed his beautiful experiments on the properties of what he called radiant matter, he could scarcely have foreseen the immense importance which such experiments were destined to assume before the close of the century. Nor could he then have suspected that the Cavendish Laboratory, inaugurated in 1874, would become the focus of the world's researches on pure electricity.

The influence of Cambridge upon electrical science since the foundation of the Cavendish Laboratory and the chair of experimental physics, has been unexampled and unrivalled. Glasgow through Kelvin, Leyden through Lorentz, Liverpool through Lodge, Manchester through Moseley, and Berlin through Helmholtz, Planck, and Einstein, have made great contributions to electrical fact and theory, but the galaxy of talent which has followed in the footsteps of Maxwell on the banks of the Cam must surely be generally acknowledged as the finest team yet engaged in the elucidation of a special branch of physics.

The importance of the work of Clerk Maxwell lay in the unification of two disciplines—those of light and of electricity respectively. It passed through several phases, in which the ultimate analysis of the phenomena then known was based upon more or less mechanical models with an underlying conception of essential continuity. Such continuity was a legacy of Faraday's recognition of the importance of the medium across which electric and magnetic forces are transmitted.

It lent a new significance to the conception of a luminiferous ether, and although the idea of a grainless continuum must always have presented certain philosophical difficulties, there is no doubt that it had a considerable heuristic value both in optics and in electromagnetism.

It does not detract from the great tradition of the Cavendish Laboratory that Sir J. J. Thomson's most noteworthy achievements have pointed in the opposite direction. His discovery of the electron in 1897 brought about a fundamental change in the ultimate conceptions of physical science. How radical was that change can only be realised by those whose electrical training took place in the 'eighties. Their preoccupation then was with the vectors and stresses in the electromagnetic field, with mechanical and hydrodynamical analogies, with sources and sinks, with the slip of lines of force on a conductor. Instead of all this, the new science of physics gives us electrons and positive nuclei, ionisation in gases, in liquids, and in solids, the emission of 'naked electricity' from hot wires, the collapse of electronic orbits, and the discrete structure of energy. Could a revolution be more complete; and the revolutionaries are the successors and disciples of the man who conceived the continuous electromagnetic ether and identified it with the all-pervading vehicle of light!

Nor can any one deny that this change of front has been exceptionally fruitful. The arch-revolutionary himself, who is now the revered Master of Trinity, devised the most powerful method of chemical analysis yet known, that positive-ray method which in the hands of Aston has brought about a new era in chemistry and shed a flood of light on the constitution of the atom and the true meaning of atomic weight. It has revealed the underlying unity of chemical substances, and has justified the bold guesses of Prout and Crookes, both of whom contended that all substances are derived from the same fundamental substance.

The Cavendish Laboratory, though one of the oldest of physical laboratories, is by no means the best equipped. Many of the new universities can boast of a better provision of expensive and up-to-date apparatus, and a few of them are far better designed. The more powerful electrical corporations, both in Europe and America, have magnificently equipped research laboratories. But tradition counts for much, even in pure science, and the habitual cultivation of science for its own sake imparts a breadth of outlook and of enterprise which is foreign to institutions working under a perpetual utilitarian effort.

We may confidently expect that Cambridge, under the guidance of Sir Ernest Rutherford, will regard the complete elucidation of atomic structure as its main function; and this elucidation may produ
some very unexpected results. For no one can s
that physical conceptions have settled down into
groove, as they seem to do after some revolutio
Quite the contrary. For the science is actually in
state of acute crisis. Never has its instrumental pow
been greater, but each new method of research see
to lead us to new and formidable problems. Einstei
conceptions of the universe as a four-dimensio
manifold of space and time have gained ground rapidl
especially since the corroboration of his astronomi
predictions by photographs taken during total sol
eclipses. They have gained ground in spite of t
greatest reluctance of the older physicists to give
their Newtonian principles. They have won the d
in spite of several serious and fundamental modificatio
introduced by Einstein himself in his original argumen
These modifications have not cancelled his main thes
and time is no longer independent of space, or spa
independent of time. Gravitation is a form of inerti
and produces a sort of kink in space impossible
conceive and impossible to formulate in terms
ordinary geometry. No wonder there are still so
physicists of the old school who think that th
cherished science has gone awry, and have given
all theorising in the expectation of better days.

Another powerful German challenge to accept
views came from Max Planck, whose conception
'quanta' of energy has been more readily accept
than relativity, solely because we happen to live in
era which looks for discontinuous structure everywhe
If the value of a physical hypothesis is to be measur
by the extent of the field covered by it and by
success in connecting phenomena previously isolat
then the quantum hypothesis must be accorded a ve
high rank indeed. For it provides a link betwe
such hitherto unrelated things as specific heat, atom
volume, photoelectricity, series spectra, and the dec
of radioactive substances. Even if it were not tr
it would deserve to be so, and it might be adjudg
ben trovato on account of its quickening effect up
research. Much remains to be done, however, befo
the new views have been linked up with the o
A multitude of questions remain to be solved. If
energy is transferred in discrete quanta, what is t
nature of such a quantum? What is its form
structure while it is on its way from one materi
system to another? Is it a wave-train? And if
what is it that undulates?

The physical theories prevalent in 1870 would ha
unhesitatingly ascribed the undulation to a fix
ether resembling in many respects a stiff jelly, b
otherwise permeable to ordinary matter. Twen
years afterwards, an incompressible continuum havi

many analogies to water would have occurred to most physicists when asked to provide (as the late Lord Salisbury asked them in his presidential address to the British Association at Oxford in 1894) a nominative case to the verb 'to undulate.' Einstein's 'gesture of despair' in renouncing all hope of ever discovering a phenomenon which would exhibit the ether drift demanded by many ingenious experimental arrangements led to a widespread abandonment of all ether hypotheses, on the plea that a substance the existence of which could not be proved might as well not exist at all.

The generalised theory of relativity more recently formulated by Einstein does, in effect, re-introduce the ether as the bearer of gravitational and electromagnetic energies, but it is an ether which remains inaccessible to any analysis based upon the classical mechanics. The same defect—if it is a defect—attaches to Niels Bohr's beautiful model of the hydrogen atom consisting of a positive nucleus with its valency electron in one of several possible orbits. The change from one orbit to the next is attended by the emission or absorption of one energy quantum, the value of which is in exact proportion to the frequency of the radiation. This model has been completely successful in explaining the spacing of the spectrum lines of hydrogen, but no one can say why the model should be so constituted. Attempts have been made, notably by Schrodinger, to formulate a new system of mechanics, provisionally called 'undulatory mechanics,' which shall be founded upon atomic phenomena rather than upon those large-scale observations which since Galileo have provided the foundation for mechanical hypotheses.

All this, however, is yet in embryo. Practical physicists concern themselves less with theoretical foundations than with the applications of a ready-made hypothesis which appears to provide a valuable guidance through unexplored mazes; and so they try the new weapons furnished by the quantum theory on all sorts of things, the excitation of line and band spectra, catalysis, photochemistry, X-rays, heat radiation, absorption spectra, and countless other matters. Some of them even attempt to count the quanta emitted by a feeble radiator by allowing them to impinge upon a fine metallic point and observing the photoelectric flash produced. Such experiments, first initiated by Geiger, will no doubt be followed up soon. The human eye, gazing upon a sixth-magnitude star, receives several hundred quanta per second. It is just possible that its insensibility to anything below that brightness is the result of a long evolutionary adaptation. For the utility of vision must depend upon the constancy of the visual impression of a point fixed in space, and an eye provided with a much greater sensitiveness would defeat the object of vision by revealing discontinuities in the light itself, due entirely to its discontinuous structure.

There is little doubt that practice will rush ahead of theory. The conception of a magneton or elementary magnetic moment, first advanced by Weiss and Langevin, has been elaborated by Bohr on the basis of his hydrogen model, and may yet do for magnetism what the electron has done for electricity. But experimentalists appear to be content with the slenderest guidance by hypothesis. They are tackling the constitution of crystals, the refraction and dispersion of Röntgen rays, and the artificial disintegration of the atomic nucleus without pausing to ask themselves for a clear conception of what they are doing or whither their results will lead. If we may follow Jeans in his graphic exposition of conditions in the distant bowels of space, we may rest assured that the most astounding discoveries made in our laboratories will fall short of those hidden in the interiors of distant stars and nebulæ, where unknown elements heavier than uranium are generated from unknown power sources, where substances have densities amounting to tons per cubic inch, where matter dies in a burst of radiant energy, and is born again by a process as mysterious as time itself.

The younger generation of physicists may well be envied. So far from being confined in their discoveries to the 'third decimal place,' they have before them an untilled field in which the transition from the apparently unknowable to the knowable, and from the knowable to the known, is not only rapid, but is also undergoing a constant acceleration.

A Half-way House of Science.

Tierpsychologie: vom Standpunkte des Biologen. Von Prof. Dr. Friedrich Hempelmann. Pp. viii+676. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1926.) 36 gold marks.

THE rival camps of mechanists and vitalists have been struck, the contending parties have advanced to meet one another, holding out the 'right hand of fellowship,' and are jointly engaged in constructing a half-way house, a shelter for those who wander on the path between biology and physiology. Here, in this shelter, the teaching of the school of animal psychology and its new technique can be imbibed. Its fundamental study has commanded attention, since interest in the phenomena of living matter was first aroused, but its establishment as a science is of recent date, and is at present much handicapped by the incompleteness of the physiological record of structure and function. The *Sturm und Drang* period in the history of science is now passed, and a stage entered upon where the accumulation of knowledge by careful individual effort adds stone after stone to an ever-growing structure. The *Zeitgeist* seems to call for a survey of the work done on animal psychology, and with this object in view Dr. Hempelmann prepared his book. A glance at the exhaustive bibliographical section will show at once with what thoroughness and conscientiousness he has attacked the work.

The physiological aspect of the subject is necessarily of primary importance, and as an assemblage of such data alone the book would be valuable. Dr. Hempelmann points out that it is useless to compare the nervous systems of invertebrates and vertebrates structurally, for too many branches have been lopped off the evolutionary tree and lost. Functionally, it is possible to adopt the human brain as a criterion, and given that it functions as a centre for (1) the summation of stimuli, (2) associative thought and memory, (3) initiation of spontaneous behaviour, (4) maintenance of muscle tone, (5) reception of sensory stimuli, to trace these functions back to their earliest appearance, collectively or singly, in simpler animal forms.

The first section of the book is devoted to these considerations. The experimental work done on the various phyla of the animal kingdom is collected here and reviewed, and immediately, while dealing only with the Protozoa, the complexity of the problem becomes apparent. Even in the Amœba it is impossible to discriminate between 'cause and effect'; the reactions of the animal are indirect, *i.e.* external stimuli induce internal changes in the protoplasm, and these in their turn produce visible reactions. These internal protoplasmic changes are also variable owing to nutritive and respiratory mechanisms, yet continuous adjustment enables the habit and behaviour of the animal to remain constant, not only in one individual, but also throughout successive generations.

Increasing complexity of structure enables the ciliate and flagellate Protozoa to exhibit an increasing variety of reactions. There is no power of discriminating between stimuli, since they automatically exhibit the whole sequence of reactions, until a suitable one is arrived at, even after continued stimulation in the same way. This method of 'trial and error' (Lloyd Morgan) results in increased efficiency of reaction which, according to some workers, may indicate the glimmerings of very primitive memory, but is more generally interpreted as being due to greater power of automatic co-ordination.

Dr. Hempelmann urges the importance of applying Loeb's theory of tropisms only in its strictest sense. Response to stimuli, being explained as a chemical reaction, presupposes the organism to be either unicellular or else of very simple structure. Higher animals, with greater complexity of structure, cannot be said to exhibit tropisms in the true sense of the word.

Clearly, then, to the simplest animals, their external life must consist of those things in the environment which stimulate the senses. The reactions which this environment calls forth in the nervous system depend on the degree of complexity of structure. These reactions, together with the internal physiological processes which they invoke, constitute the inner life of the animal (V. Uexküll). With the development of a head, and the concentration of ganglionic masses in this region, as in worms, higher control of these reactions probably comes into existence, and with the appearance of an elaborate eye, as in the Cephalopoda, calculated movements can be made. The exact significance of perception cannot be gauged—as V. Uexküll remarks, it is impossible to determine whether the animal perceives an external world of light-spaces and dots, or a cerebral world of water, land, etc.

The great specialisation of the body in the Insecta has led to a corresponding specialisation of the nervous system. All action is still instinctive, although great plasticity is displayed, which gives the appearance in some cases of controlled action. Recognition of objects, and hence memory, is shown by the homing powers and activities of bees, etc.

Associative thought, power of recognition, and memory are manifested by vertebrates to a varying degree, and above the Amphibia, purposeful action, *e.g.* as in the search for food, is met with. The warm-blooded birds and mammals appear more active and have a greater range of plastic instincts, which leads to a highly developed associative memory.

The effects of domestication are sometimes advantageous, sometimes disadvantageous to the animal. Instinctive reactions are part and parcel of the type of animal body. A greater or less power of co-ordination of sensory impressions with body movement constitutes the degree of education and stimulation. Certain reactions will be found to be an actual structural impossibility for some animals to perform, and these animals are probably judged as being 'less intelligent' than others more plastically designed. Dogs, if possessed of fore-limbs like a monkey, would probably prove more teachable, although the process might be a slower one. Apes lack application and are easily deflected from the business in hand; but they learn to do a thing suddenly, and after that generally perform it correctly. It is questionable whether this lack of application does not indicate a more marked individuality, and is, hence, a sign of greater mental development or of higher consciousness.

The question of higher consciousness is dealt with, in comparison with the psychology of man, in the econd part of Hempelmann's book, and involves much epetition of what has gone before. This division of he subject into what might be termed the mechanistic and vitalistic aspects does not make for clearness or brevity, and the first special section would have been more appropriately included under the sub-headings of the second general section. In the present state of our knowledge we are not in a position to attempt to discriminate sharply between instinctive and controlled behaviour, as Dr. Hempelmann remarks. Yet from the arrangement of his book this is what he would appear to wish to do. As a result, the information is scattered, and the index does not help very materially in its co-ordination.

Such problems as the homing instinct, sense of numbers, 'thinking animals,' and so forth, are discussed. The explanation in the case of the first two probably lies in the recognition by the animal of the 'look of the thing,' and in its perception of some expression, conscious or sub-conscious, on the part of the master in the last case. Bühler's suggestion that a slight sense of time is developed in predacious animals, since they are able to judge the interval which elapses between disappearance and reappearance of their prey behind trees, etc., is an interesting one.

The subjective side of animal life can only be examined by analogy with that of man. Even the primitive sensation, pain, with its corresponding emotion, fear, cannot be accurately gauged. How much reaction is due to the stimulus, and how much is due to the inherent excitability of nervous tissue, it is impossible to say. The Arthropoda appear insensible to pain and continue their avocations though seriously maimed, and frogs exhibit ordinary 'pain' reflexes when the higher nerve centres have been destroyed. The sensation of pain is usually associated with the 'free' nerve endings in the skin of higher vertebrates, birds, and mammals. Ziegler denies its existence as a separate sensation, and there is difficulty in distinguishing between the touch and pressure centres, etc., in the skin. V. Uexküll, on the other hand, regards it as a biological necessity, having a definite place in the scheme of things, while Plate believes it is primitively developed in the Metazoa. Research shows that the physiological occurrences which accompany sensations and emotions in man occur similarly in animals. In man, these sensations are regarded as manifestations of higher consciousness, and though we must credit their similar occurrence in animals, we may be far from allowing the latter a similar possession of consciousness. Only the higher vertebrates show signs of this, and then only by analogy with man; yet it is impossible to say what processes are lacking to make its presence dubious.

Physiological occurrences, as at present understood, do not explain all the phenomena of living matter, and this realisation is at the root of vitalistic theories, which postulate some extra force or factor, entelechy, élan vital, cell intelligence, and so on. Since man is conscious of the possession of a directive will, he tends to see manifestations of the same force among the animals. As Dr. Hempelmann points out, this introduces the danger of anthropomorphism into the subject. In the words of the Chinese story: "'How delightfully the fishes are enjoying themselves!' exclaimed Tschuang-Tse, while walking on the bank of a river with Hui-Tse, who rejoined: 'You are not a fish; how do you know that the fishes are enjoying themselves?' 'You are not myself,' returned Tschuang-Tse, 'how do you know that I do not know that the fishes are enjoying themselves? I know because of my own pleasure in the water.'"

Helene E. Bargmann.

Alchemy and Mysticism.

The Secret Tradition in Alchemy: its Development and Records. By A. E. Waite. Pp. xxii+415. (London: Kegan Paul and Co., Ltd.; New York: Alfred A. Knopf, 1926.) 15*s*. net.

THERE are two varieties of alchemical literature, which may be roughly described as mystical and practical. The former employs the terms of alchemy in a figurative sense in the attempt to convey the ineffable, to picture the soul's progress along the Way, and to delineate the states of ecstasy which are common to the mystics of all nations and religions. The practical books, on the other hand, are exactly what they profess to be, namely, text-books of chemistry in which the principal theme is the transmutation of the metals. If this were all, there would be no particular difficulty in deciding to which of the two classes any given book should be assigned, and the task of the historian of chemistry—or of mysticism—would be correspondingly lighter. Unfortunately, however, the actual state of affairs is not so simple, for there is no sharp line of demarcation which divides the alchemical allegory from the text-book of chemical transmutation.

It is not difficult to understand how the confusion may have arisen, for there were two factors at work which would almost inevitably cause it. In the first place, the distinction which we now recognise between physics and metaphysics was not clearly defined in the middle ages, and Aristotle's postulation of a *Fifth Essence* afforded a convenient basis for occult speculations of all kinds. It is significant that the greatest of early chemists, Geber, was also a member of the mystical order of Sufis, then newly founded, and that mastery of alchemy was considered to be acquired by direct or indirect inspiration from divinity itself. Secondly, the belief that lead, tin, and the other base metals were diseased or imperfect forms of gold and silver which could be cured or perfected by elixirs soon led to an exaggerated idea of the supposed powers of the latter. Besides healing the metals, why should they not be able to cure man of his bodily infirmities, since man is composed of the same four elements combined in a not very dissimilar way? We do in fact find that, even so far back as Geber, the medicine of metals is also the medicine of man, which will cure him of all disease and restore him to that state of equilibrium which is health. From this stage to the final conclusion that there must be a spiritual alchemy which would do for the soul of man what the most noble elixir did for his body, was but a short step.

The outcome of this intricate interweaving has been that chemists have tried to read experimental facts into allegorical descriptions, and have failed, and that students of mysticism have tried to read allegory in laboratory notebooks, and have succeeded. In other words, a school of thought has arisen which claims that all alchemical books, not merely a section of them, deal with spiritual alchemy, and that to interpret them in their literal sense is to go astray. It is very difficult to understand how such a position can be seriously maintained, but we should perhaps not be unduly surprised that it has been taken up when we remember the 'Bacon-is-Shakespeare' thesis and the occult interpretation of the Great Pyramid.

It is, therefore, with genuine pleasure that we welcome Mr. Waite's book, in which he has set himself the problem of ascertaining as conclusively as possible the grounds upon which the extravagant claims just described are based. No one could be more fitted for the task than Mr. Waite, whose knowledge of occult literature of all kinds has probably never been surpassed, and who will certainly not be accused of undue bias toward the literal interpretation of alchemy. "The transmutation of metals *per se*," he says, "is no concern of mine; but it has been said that great secrets of the soul are hidden under veils of *Chemia*; that they are of a kind which called for concealment in those persecuting days when the literature came into being; and that even now—when things are proclaimed on the housetops which used to be whispered in crypts—it is impermissible to speak of them openly because they are liable to abuse."

It is clearly of great importance that the question should be settled one way or the other, for if alchemical treatises are nothing more than rhapsodies of the mystic, the historian of chemistry is wasting his time when he investigates them. Hence, although the answer Mr. Waite gives may be guessed beforehand—since according to the mystical school, chemistry must have sprung into being fully armed at some undetermined period—he has done good service in exposing the pretensions to a searching and ruthless criticism. He first examines the alchemical literature of the Greeks, Byzantines, Syrians, Arabs, and Persians, and shows that, obscure though the language and vocabulary may be, the subject matter is definitely concerned with physical, metallic transmutation or with such technical matters as dyeing, metal-working, and the like. Marvellous medicinal properties of elixirs are mentioned less frequently, but that alchemy was undoubtedly a branch of contemporary natural science is demonstrated with an unassailable logic. Medieval Latin alchemy, in the cold light of this analysis, yields the same results.

According to Mr. Waite, it is only with Heinrich Khunrath (1560–1605) that the mystical variety of alchemy definitely began. Khunrath, he says, "is concerned solely with an *itinerarium mentis in Deum*, and because he was an alchemist he used things seen, imagined, or reported in the process of the Stone to illustrate—as he understood them—the states and stages of the soul's ascent upward. To adopt popular terms, it follows that the *Amphitheatrum Sapientiae Aeternae* is a Book of Divine Alchemy, and it is of great importance, not only because the physical aspects of the Art dissolve continually and are intended to merge in the spiritual, but most especially because it is the very first of the kind." The well-spring and fountain-head of spiritual alchemy was Jacob Boehme, who began to unfold his revelations in 1610, by which time physical alchemy was about to merge into chemistry proper. The later developments of the fashion set by Khunrath and Boehme need not detain us; no historian of chemistry has ever been misled by them, and their study belongs rather to occultism than to the history of science.

Mr. Waite has, in short, finally and irretrievably demolished the fantastic thesis set up by Mrs. Atwood and others, and has proved beyond refutation that early and medieval alchemy was almost entirely concerned with physics or physic. Our only criticism is that he has perhaps overstated his case in referring the origin of spiritual alchemy to so late a date as that of Khunrath, for the great mystic of Islam, Al-Ghazzali (died A.D. 1111), had already applied the terms of alchemy to the life and progress of the soul, though in such a way as to cause no confusion to any one except him who set out to be confused.

E. J. HOLMYARD.

John Barleycorn.

The Barley Crop: a Record of some Recent Investigations. By Dr. Herbert Hunter. Pp. viii+166. (London: Ernest Benn, Ltd., 1926.) 10*s.* 6*d.* net.

THIS little book serves to illustrate a thesis which frequently finds expression in this journal—that science embraces more than the mere ascertainment and enunciation of the laws of Nature: it connotes a logical system universal in its application. When in 1900 the Irish Department of Agriculture, in association with a leading firm of brewers, set out to solve the problem of what is the best barley to grow in Ireland, they attacked it scientifically. They cleared the ground of so-called practical opinions depending, as they do so often, on irrational ideas and traditions, and from the outset employed the tools upon which, as Kelvin once declared, all accurate scientific work must be founded, namely, weighing and measurement.

After upwards of twenty years of careful work, a variety of barley was found which can be proved to be best, and, as a matter of fact, it now occupies 90 per cent of the total area under the crop in that country. It is a further tribute to the value of scientific work that the variety of barley in question was ultimately made 'according to plan' by the application of the discoveries of Mendel to the problem. The author of the work under notice, Dr. Hunter, to whom the credit of the final achievement is due, has an interesting story to tell, and it is a story with a lesson for the plant-breeder and administrator with a definite economic object in view; a lesson, moreover, learned and practised in other countries which (like Ireland in pre-War days) possessed a Government ready to adopt the teachings of the scientific worker.

The finding and making of a super-barley followed what is now a well-trodden path: first, the recognition that the age-old varieties of the farmer are populations of various genetic types; the isolation of pure lines by propagation from a single plant; and, finally, the crossing of two pure lines in order to effect an exchange of desired characters. The first ten years were spent in isolating a pure line of "Danish Archer" barley as the best of existing types, giving both yield and quality, but possessing a weak straw: the next five in extracting the stiff straw from "Spratt" barley, transferring it to "Archer" and building up a stock of seed, starting again, be it noted, from a single plant. In the end, as already noted, nearly 100 per cent. of the barley area in Ireland is now sown with "Spratt Archer." Note also that when the original plans were laid in 1900, Mendel had just been re-discovered, Johannsen's pure line had not been heard of: scientific methods were the only guide.

There was much the same story to tell in noticing Mr. A. Howard's book on "Crop-Production in India," and there also the plant-breeder's work has been exploited by the State. As Mr. Howard has said, the making of a new variety is futile, unless some means of introducing it to the farmer can be definitely organised. Nor is it less important, as Dr. Hunter points out, to provide for a continuous flow of pure seed ever after.

A few words of criticism: Dr. Hunter does not indicate what the desired quality of barley, other than low nitrogen content, may be, or the part played by diastase in the malting process. It is not quite clear, either, what effect various manurial treatments of the soil may have on quality. In a future edition it might be well to bring the statistics of barley acreage and yield in Ireland down to a later date than 1922. Finally, a problem is suggested by the graphs of nitrogen content and yield. May it not be the case that high nitrogen content of the seed promotes vigorous growth and that, consequently, a super-excellent malting sample (within the line) is not necessarily a good mother for the resulting plant? We seem to recollect some work of Dr. Beaven (of barley fame) which suggests this query.

We must compliment the author not only on a successful piece of work, but also on the interesting account he has written of its progress and results. It should prove of extreme interest to the enlightened farmer, the professional plant-breeder, and even to the ordinary men, who, through the ages, have hymned John Barleycorn and his products! A. B. B.

Labour Policy in Education.

From Nursery School to University: a Labour Policy. Report of the Education Advisory Committee of the Trades Union Congress and the Labour Party. Pp. 93. (London: Trades Union Congress and the Labour Party, n.d.) Paper, 6*d.*; cloth, 1*s.*

THE little book which has just appeared with a foreword by Mr. Ramsay MacDonald follows lines now well understood in the matter of labour zeal for public education. It is the strongest side of Socialist policy, and all those who have experience, either official or private, with educational work, will testify that members of the Labour Party are foremost everywhere in their efforts to promote the education of the people.

Those who feel compelled to take a somewhat critical attitude will fasten on three points in the manifesto before us which give occasion to pause, if not actually to oppose the steps proposed. The first, and to most people the most serious, difficulty is dealt with in the last section of the pamphlet. It lies, of course, in the expenditure involved. The detailed proposals would raise the educational budget by about fifty per cent., making the total equal to the expenditure on army, navy, and air forces combined—*i.e.* just over a hundred millions a year. No one can on principle complain of that, but the proposition will assume a rather different aspect to a Chancellor of the Exchequer who has to raise the money from a country clamouring for a reduction in taxation, and in face of the strongly organised bodies of opinion which demand the maintenance of the other types of expenditure.

The question is, in short, a matter of the balance of public opinion which every government has ultimately to follow. The same consideration occurs when the writers point out that we actually spend more both on tobacco and on drink (separately) than the total they propose for education. Here, of course, the spending is in our own hands. We do as a nation prefer to spend all that money on smoke and drink rather than on books or pictures or going to concerts, and, so long as we do so, it is still less likely that we shall be willing for the government to take the money away from us in order to spend it on some purpose which some members of it think better.

There is another consideration of rather wider bearing which arises from the memorandum. The policy suggested throughout is for the State to do all that is wanted out of public funds. It is urged that all secondary schools should be free, and every one should be encouraged, if not compelled, to go to the State preparatory schools.

This encouragement has, as a matter of fact, become practical compulsion in some other countries, notably in the more socialist parts of Germany, but it would be, we are convinced, both a grave mistake and very repugnant to the free spirit of England. The practical problem for wise statesmanship in England is to combine State encouragement and financial help to education with the freedom of choice and teaching which we have always followed, and with the private generosity which has done so much in the past and is by no means wanting in the present.

The pure educationist will raise one more question when he reads of the hosts of new teachers who will be needed to carry out the vast extension of secondary schools and the further limitation of the size of classes. Both excellent things, ardently to be desired, but, in view of the supreme importance of good teachers, will it not be wise as well as necessary to go a little slowly?

The Outline of History: a Plain History of Life and Mankind. By H. G. Wells. New edition, fully revised. Parts 1-24. (London: Cassell and Co., Ltd., 1925–1926.) 1*s.* 3*d.* net each part.

Mr. Belloc objects to "The Outline of History." By H. G. Wells. (The Forum Series.) Pp. vii + 55 (London: Watts and Co., 1926.) 1*s.* net.

ON the appearance of the first number we directed attention to the new edition of Mr. H. G. Wells's "Outline of History," the serial issue of which has recently been completed. The "Outline" has been almost entirely rewritten, brought up-to-date, and provided with a fresh set of illustrations—perhaps as remarkable a collection of photographs covering all sides of human evolution and history as has ever been gathered together within the covers of one book. Apart from matters of opinion, in which Mr. Wells is characteristically individual—it is emphatically Mr. Wells's outline of history—there is little even in matters of detail which requires criticism. To have mastered so vast a body of material, and to have kept abreast of current opinion on so many technical subjects, is in itself no small intellectual feat. To take an example only, he is prepared to assign the Taungs man a place in his evolutionary scheme, although this skull was discovered only while the book was in process of writing. On certain points in dealing with the bronze and iron ages, and on ethnological questions relating to the origin and migrations of races, the views adopted by Mr. Wells are open to argument, just as his views of great personalities, such as Alexander, Julius Cæsar, or Napoleon, invite or even provoke discussion. These, however, are little more than matters of detail in relation to the broad scheme of evolutionary history which Mr. Wells has set himself to expound.

To those, be they men of science or historians, who grasp the broader issues of biological and anthropological science, Mr. Wells may seem neither revolutionary nor iconoclast; but it is evident that the "Outline" has been a stumbling-block to a certain type of orthodoxy. Criticisms of Mr. Wells and his views by Mr. Hilaire Belloc have appeared in certain Roman Catholic newspapers *pari passu* with the fortnightly issue of the "Outline." Mr. Wells, having failed to secure adequate opportunity for reply in the periodicals in question, now replies in a little volume which he has issued himself. It is scarcely necessary to say that Mr. Wells's humorous, if caustic, pen makes short work of Mr. Belloc's criticisms as well as his views on the subjects of natural selection, evolution, and the ancestry of man.

Pitman's Building Educator. Edited by Richard Greenhalgh. Complete in 30 fortnightly parts. Part 1. Pp. ii + 56. (London: Sir Isaac Pitman and Sons, Ltd., 1926.) 1*s.* 3*d.* net each part.

THE aim of this publication is to cover the whole range of work embraced not only under the term 'building,' but also architecture. Modern buildings require an extraordinary range of services for which an architect takes responsibility, and the task imposed in an endeavour to cover this field, even in a work which, it is presumed, will eventually comprise some 160 pages, is no light one. Among the editor's forty contributors appear the names of a number of leading men in the architectural and engineering professions who have each taken a subject upon which progressive articles will appear in successive issues, and the editor points out that many ordinary text-books are incomplete and that certain administrative and commercial aspects of building work have been much neglected by writers in the past, which gaps it is proposed to fill.

The issues will deal with such diverse subjects as architectural design, builder's accounts, gas fitting and building law. Opinions may differ as to whether the presentation of so many subjects in articles of only two or three pages is the best method of education, inasmuch as these subjects are obviously not equally suitable for study at one particular age, but a selection of articles is suggested for the special perusal of the aspiring architect, surveyor, builder and engineer.

The work is well illustrated by photographs and cuts and well printed, but we think that the compilation which involves back references, such as an article on superintendence continued on page 31 from page 49, open to criticism. A full index is promised on the completion of the publication, which should reduce the labour of a student wishing to traverse the ground of a particular subject with the thirty parts before him.

The Evolution of the Horse. By Prof. F. B. Loomis. (The Amherst Books: Second Series.) Pp. xvi + 233 + 26 plates. (Boston, Mass.: Marshall Jones Co., 1926.) 3 dollars.

For the Mammalia the family of horses has long been the standard example of an evolutionary series. There is no doubt that of all such series it is the most completely known and that it throws much light on the manner, if not on the method, of evolutionary change in mammals. Properly to understand this change, and the theoretical arguments which arise therefrom, it is necessary that the available data should be presented in considerable detail. The majority of text-books fail in this respect from lack, no doubt, of sufficient space. A summary of what has happened in some millions of years (forty-five millions according to the present author), illustrated by perhaps a dozen examples of horses chosen from successive strata to form a gradated series, cannot give a true impression of the facts. There is, moreover, a danger of such series becoming stereotyped, and for the student in consequence to come to think that it represents the whole picture and so to remain ignorant not only of the wealth of material that has been collected together but also of the fact that the horses, so far from being a straight line of evolution, and no more, had, on the contrary, many lines adapted in different ways, some successful, others the reverse.

Prof. Loomis has contributed to our knowledge of the horses, not only by original work in the field, but also by the publication of a small book which will help in some measure to correct the mistaken views adverted to above. It should be useful in the hands of the student, and is not too technical for the layman who is interested in the subject. Within the limit of some two hundred pages the family is traced from its beginning in the Eocene period up to modern times. The twenty-six plates are good, but the text figures, while adequate, are perhaps not up to the usual standard of artistic excellence of American palæontological publications. Here and there the specialist may find a statement with which he is not in complete accord, but as a general account, Prof. Loomis's book can safely be recommended.

Tabulae Biologicae. Herausgegeben von C. Oppenheimer und L. Pincussen. Band 2: *Thermochemie, Physikalische Chemie der Fermente, Elektrizitat und Elektrochemie, Strahlenlehre, Spezielle Biophysik, Sekrete.* Pp. viii + 567 + 25 Tafeln. (Berlin: W. Junk, 1925.) 55 gold marks.

The "Tabulae Biologicae" gives in compact tabular form the data which have been accumulated by many authors in all branches of the biological sciences. In addition, information is given on certain aspects of related sciences, where knowledge of the latter is a necessary preliminary to the performance and evaluation of biological experiments: for example, in this, the second, volume, the electrical section includes data on the electrical properties of metals, dissociation constants, and the pH values of different solutions. Data are also given on X-rays, radioactivity, and the spectral energy of lights of different wave-lengths. The kinetics and conditions of activity of the different enzymes are very fully treated.

Among the other subjects dealt with, attention may be directed to the data on the special senses and the physiology of muscle and nerve: tables of the actions of drugs on the vegetative nervous system and plates of the physiological anatomy of the central nervous system are included. The composition of the following will also be found in this volume: blood, skin, the digestive secretions, lymph; cerebrospinal fluid and transudates, milk. We note a useful table of the structure of the salivary glands in different animals. Although possessing a strong Teutonic flavour, the volume may be thoroughly recommended as an extremely useful work of reference. A fairly full table of contents acts also as an index.

Die intraindividuelle fluktuierende Variabilitat: eine Untersuchung uber die Abanderung des Pflanzenindividuums und die Periodizitat der Lebenserscheinungen. Von Prof. Dr. E. Dennert. (Botanische Abhandlungen, Heft 9.) Pp. 149. (Jena: Gustav Fischer, 1926.) 7 gold marks.

Whereas most of the statistical work on fluctuations (Darwin's individual variations) has related to their occurrence in a race or species, the author has focussed his attention upon fluctuations within the individual plant. His extensive data are derived from measurements of leaves and various floral parts, as well as by counting the numbers of ray-florets in two species of Aster. The conclusion is reached that extra-individual fluctuation is a summation of the fluctuations within the various individuals and that the two phenomena are identical. The graphs in all cases betray a definite rhythm, a rise to a maximum and a subsequent fall to a minimum, but the fluctuations show slight differences in character which can be reduced to three principal types. In the final section the author concludes that the ultimate causes of this fluctuation are inherent in the protoplasm, but that its manifestation, and to some extent also its special character, are dependent on external and internal factors.

The Conservation of Photons.

WHATEVER view is held regarding the nature of light, it must now be admitted that the process whereby an atom loses radiant energy, and another near or distant atom receives the same energy, is characterised by a remarkable abruptness and singleness. We are reminded of the process in which a molecule loses or gains a whole atom or a whole electron but never a fraction of one or the other. When the genius of Planck brought him to the first formulation of the quantum theory, a new kind of atomicity was suggested, and thus Einstein was led to the idea of light quanta which has proved so fertile. Indeed, we now have ample evidence that radiant energy (at least in the case of high frequencies) may be regarded as travelling in discrete units, each of which passes over a definite path in accordance with mechanical laws.

Had there not seemed to be insuperable objections, one might have been tempted to adopt the hypothesis that we are dealing here with a new type of atom, an identifiable entity, uncreatable and indestructible, which acts as the carrier of radiant energy and, after absorption, persists as an essential constituent of the absorbing atom until it is later sent out again bearing a new amount of energy. If I now advance this hypothesis of a new kind of atom, I do not claim that it can yet be proved, but only that a consideration of the several objections that might be adduced shows that there is not one of them that can not be overcome.

It would seem inappropriate to speak of one of these hypothetical entities as a particle of light, a corpuscle of light, a light quantum, or a light quant, if we are to assume that it spends only a minute fraction of its existence as a carrier of radiant energy, while the rest of the time it remains as an important structural element within the atom. It would also cause confusion to call it merely a quantum, for later it will be necessary to distinguish between the number of these entities present in an atom and the so-called quantum number. I therefore take the liberty of proposing for this hypothetical new atom, which is not light but plays an essential part in every process of radiation, the name *photon*.

Let us postulate for the photon the following properties: (1) In any isolated system the total number of photons is constant. (2) All radiant energy is carried by photons, the only difference between the radiation from a wireless station and from an X-ray tube being that the former emits a vastly greater number of photons, each carrying a very much smaller amount of energy. (3) All photons are intrinsically identical. As the molecules of hydrogen differ from one another in direction and energy of translation, and in direction and amount of rotation, so two photons, as seen by a single observer, differ in direction of motion, in energy, and in polarisation. If we were moving with rapid acceleration toward a wireless station, its photons would appear to possess increasing amounts of energy, and would pass over the whole spectral scale through the visible and into the ultraviolet. At a certain instant, for example, they would be indistinguishable from the photons emitted by excited sodium atoms. (4) The energy of an isolated photon, divided by the Planck constant, gives the frequency of the photon, which is therefore by definition strictly monochromatic; although two photons coming even from similar atoms would never have precisely the same frequency. (5) All photons are alike in one property which has the dimensions of action or of angular momentum, and is invariant to a relativity transformation. (6) The condition that the frequency of a photon emitted by a certain system be equal to some physical frequency existing within that system, is not in general fulfilled, but comes nearer to fulfilment the lower the frequency is.

The serious objections to the idea of the conservation of photons are met in a consideration of the thermodynamics of radiation and of the laws of spectroscopy. According to the classical thermodynamics of radiation, the energy of a *hohlraum* at a given temperature is determined solely by the volume. If we define the number of photons in a small spectral interval by the amount of energy in that interval divided by $h\nu$, then, by Wien's displacement law, the number of photons remains constant in any reversible adiabatic process. Also, in the irreversible adiabatic process of free expansion from a given volume to a larger volume (both with perfectly reflecting walls) the number of photons remains constant, for neither the energies nor the frequencies are changed. If the original radiation, corresponding to a definite temperature, freely expands, let us say, to sixteen times the first volume, then, according to the thermodynamics of Wien and Planck, it may be brought to a new temperature equilibrium by introducing an infinitesimal black body. Calculating from their equations, we find that in this process the number of photons is doubled. If this is so, there obviously can be no conservation law for photons. However, if we analyse carefully the thermodynamics of radiation, we find that Wien and Planck have tacitly employed a postulate which is supported by no experimental facts; namely, if an infinitesimal black body is introduced into a *hohlraum*, the radiation will come to a certain temperature, and then *no further change will ensue* when a large black body of the same temperature is introduced.

Dispensing with this postulate, and adding a new variable, the number of photons, to the variables which have previously been deemed sufficient to define the state of a system, we obtain a greatly enlarged science of thermodynamics. In this new thermodynamics, which includes as true and stable equilibria such states of equilibrium as those to which Einstein has applied the terms "aussergewöhnlich" and "improprement dit" (*Ann. Phys.*, 38, 881, 1912; *Jour. de Phys.*, 3, 277, 1913), the familiar laws of radiation and of physical and chemical equilibrium become special cases, true only for an unlimited supply of photons. Even so fundamental a process as the flow of heat must involve two factors, the amount of energy and the number of photons transferred. A fuller account of this new thermodynamics will shortly be published.

Turning to spectroscopy, we find that the principle of the conservation of photons is in obvious conflict with existing notions of the radiation process. We must assume that in an elementary process of radiation one, and only one, photon is lost by the emitting atom. Suppose that an atom which is in the 4-2 state drops to the 3-3, then to the 2-2, then to the 1-1. It thus loses three photons, but the same atom dropping directly from the 4-2 state to the 1-1 loses only one photon. If, therefore, we are to admit the conservation of photons, we must say that the atom does not pass from precisely the same initial to the same final state by the two paths, but rather that either the 4-2 or the

1-1 states, must be multiple. Even if the inner quantum number is given, as well as the total and the azimuthal quantum numbers, the atomic states must still be regarded as not completely specified. Indeed, numerous examples have been found (see the review by Ruark and Chenault, *Phil Mag.*, 50, 937, 1925) of a superfine structure which is not yet accounted for.

I had hoped to be able to derive certain familiar selection principles from the conservation of photons. Here I have not as yet succeeded, and can only state that if we assume the existence of a number of atomic states with nearly the same energy but with different numbers of photons, the new theory is not in conflict with the results of spectroscopy.

The rule that one, and only one, photon is lost in each elementary radiation process, is far more rigorous than any existing selection principle, and forbids the majority of processes which are now supposed to occur. To account for the apparent existence of these processes, it is necessary to assume that atoms are frequently changing their photon number by the exchange of photons of very small energy, corresponding to thermal radiation in the extreme infra-red. The new theory therefore predicts that many atomic processes will be inhibited at very low temperatures, and for this there seems to be some experimental evidence. But the existence of numerous extraneous factors obscures the issue. In order to simplify matters, a molecular stream might be passed through the centre of a tube cooled to a very low temperature, so as to reduce to a minimum the amount of thermal radiation. The theory would predict that in such circumstances certain processes within the stream, such as fluorescence or the emission of light from activated atoms, would be profoundly changed. Experiments in this direction are now in progress.

GILBERT N. LEWIS.

The Synthesis and Disintegration of Atoms as Revealed by the Photography of Wilson Cloud Tracks.

IN 1923 Harkins and Ryan developed a simple method (NATURE, 112, 54; *J. Am. Chem. Soc.*, 45, 2095) for obtaining a knowledge of what occurs when an atom disintegrates. This consisted of the use of very fast α-rays, such as those of thorium or radium-C, in a modified Wilson (Shimizu) ray track apparatus, and the photography of an extremely large number of tracks. By the use of these fast rays, about 20,000 photographs in air and 21,000 in argon were obtained. Each photograph gave two views at right angles. That Wilson's apparatus had not been applied earlier for this purpose was undoubtedly due to the fact that it had previously seemed almost hopeless to obtain sufficient photographs.

In 1925 Blackett (*Proc. Roy. Soc. A.*, 107, 349), by the use of the method applied earlier by Harkins and Ryan, obtained 22,000 photographs in nitrogen. In these, eight disintegrations of nitrogen atoms to give protons were obtained, and it was found that in rare instances a fast α-particle attaches itself to the nucleus of a nitrogen atom.

The purpose of this letter is to present the results obtained from 34,000 photographs not previously reported. These contained an average of about 14 α-particle tracks each; so that about 270,000 tracks of 8·6 cm. range were obtained.

These have given two cases in which an α-particle attached itself to a nitrogen nucleus. One of the protons was emitted in a forward direction, that is, with a component of velocity in the same direction as that of the α-particle, while in the other case the proton was emitted backward.

Fig. 1 is from a photograph which was presented to the National Academy of Sciences in April 1926.

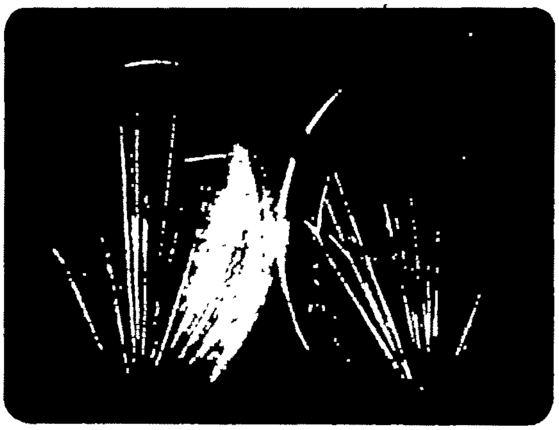

FIG. 1.—Simultaneous views at right angles of Wilson cloud tracks. In the original negative the track of the H+-particle has about one-tenth the intensity of that of the α-particle or of the oxygen of mass 17. The disintegration is shown at the left side of each of the two views, but is much more distinct in the right-hand view.

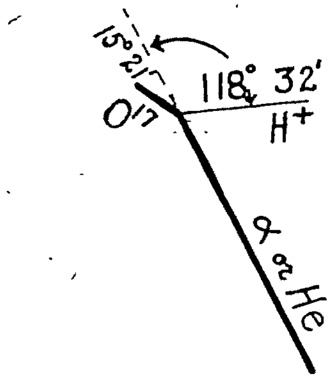

FIG. 2.—The space relations of the synthesis and disintegration exhibited in Fig. 1.

The values obtained in this case (Fig. 2) are θ, 118° 32′; φ, 15° 21′; remaining range of α-particle at time of collision, 6·3 cm.; velocity of α-particle at collision, $1{\cdot}86 \times 10^9$ cm. per sec.; initial velocity of proton, $2{\cdot}7 \times 10^9$ cm. per sec.; range of the proton, 19·6 cm., and velocity of heavy nucleus formed, $5{\cdot}3 \times 10^8$ cm. per second.

The kinetic energy after collision is 89 per cent. of that of the α-particle at time of impact, so 11 per cent of the kinetic energy is stored up in the atom (presumably oxygen of mass 17) which is synthesised.

The hydrogen track of Fig. 1 has, on the original film, only about one-tenth the intensity of the tracks produced by the helium and the oxygen. That this is actually a hydrogen track is also indicated by the fact that the visible range in the original photograph is more than three times the range for an α-particle under the same conditions.

It may be noted that we have obtained only two atomic syntheses and disintegrations in the photography of 265,000 tracks, while with the same number of tracks Blackett obtained eight similar events, which, however, the Cambridge workers consider an abnormally high number. Since we have investigated carefully every bend in the α-ray tracks, it seems improbable that we could have overlooked more than two such events.

It is of interest that the smallest velocity of the α-particle which has thus far been sufficient to disintergrate a nitrogen atom in the work at Cambridge and in Chicago corresponds to a remaining range at 15° of about 6·2 cm. Now the range of an α-particle from polonium, which was used in practically all of the early work on α-ray tracks, is only 3·925 cm. It is evident that if polonium had been used as a source, not one of the ten disintegrations thus far found would have been obtained. It was because the early work on the scintillation method indicated such a result that Harkins and Ryan changed to a source which contained thorium C′, such as thorium C, or thorium B and C.

According to Petterson and Schmidt ("Atomzertrummerung," p. 109) the α-rays from polonium liberate H-particles from aluminium, but the results cited above do not indicate this to be true in the case of nitrogen. However, it will be necessary to obtain more photographs, and to examine again those already obtained before a definite conclusion can be drawn.

A part of the measurements on the photograph (Fig. 1) were obtained by a new method, which corrects for errors in the lenses and mirrors. It is equivalent to the establishment in the ionisation chamber of a set of co-ordinates in space.

We wish to thank Mr. C. N. Shah for a considerable part of the calculations involved, and for much time spent in the examination of the films.

WILLIAM D. HARKINS.
HUGH A. SHADDUCK.

Quantum Mechanics and the Magnetic Moment of Atoms.

IN a recent paper E. Schrodinger (*Ann. d. Phys.*, 81, 1926, 109) put forward a hypothesis connecting the field scalar ψ of his undulatory mechanics with the electric density of current. His formulæ in the case of a system with only one electron (expressing j in electromagnetic units) reduce to .

$$\rho = e\psi\bar{\psi}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$j = \frac{he}{4\pi imc}(\psi \text{ grad. } \bar{\psi} - \bar{\psi} \text{ grad. } \psi), \quad . \quad (2)$$

where ρ and j are respectively the electric density and density of current. The field scalar must be normalised in such a way that

$$\int\psi\bar{\psi}d\tau = 1, \quad . \quad . \quad . \quad . \quad (3)$$

$d\tau$ being the element of volume.

Evidence in favour of the expression for ρ is given by the fact that the calculation of the intensity of emission of the atom, based on it, is in accordance both with experiment and with the results of Heisenberg's quantum mechanics. Expression (2) for j is assumed by Schrodinger as the simplest way of satisfying the equation of continuity of electricity.

It is desirable, therefore, to find some further evidence for this expression. I propose to show that it leads to the right expression for the magnetic moment of a hydrogen-like atom. We will consider only the part of the magnetic moment which, in the old quantum theory, was supposed to be due to the orbital motion of the electron, not taking into account the magnetic moment of the spinning electron, which can be considered separately.

The wave equation for a hydrogen-like atom in a magnetic field (without considering the spinning electron) was integrated by Fock (*Zeit. f. Phys.*, 28 1926, 242). His expression for ψ can be written in th form

$$\psi = f(\theta, r)e^{in_1\phi}e^{2\pi i\frac{E}{h}t}, \quad . \quad . \quad . \quad (4$$

where r, θ, ϕ are polar co-ordinates; $f(\theta, r)$ is a rea function of r and θ, n_1 is an integer correspondin to the magnetio quantum number of the old theory.

It is easily seen from (2) and (4) that j is a vecto perpendicular at each point to the plane passin through the point and the polar axis, the magnitud of which is

$$j = \frac{he}{4\pi imc}\frac{1}{R}\left(\psi\frac{\partial\bar{\psi}}{\partial\phi} - \bar{\psi}\frac{\partial\psi}{\partial\phi}\right) = -\frac{he}{2\pi mcR}n_1f^2, \quad . \quad (5)$$

R being the distance of the point from the axis. Th lines of current are circles situated in planes perpendicular to the axis and with their centres on the axis

Let us now consider the current passing throug an element $d\sigma$ of a meridian plane; its intensity is given by $jd\sigma$ and its circuit is a circle with radius R The magnetic moment of this current is therefor $\pi R^2jd\sigma$ (in the direction of the field).

The magnetic moment of the atom becomes, putting for j the expression (5),

$$\mu = \pi\int R^2jd\sigma = -\frac{hen_1}{2mc}\int Rf^2d\sigma. \quad . \quad . \quad (6)$$

The last integral can be valuated by substituting (4) in (3), and observing that $d\tau = 2\pi Rd\sigma$, we find then $2\pi\int Rf^2d\sigma = 1$. Putting this value into (6) we find at last

$$\mu = -\frac{he}{4\pi mc}n_1. \quad . \quad . \quad . \quad (7)$$

That is, the component of the magnetic moment in the direction of the field is the product of a Bohr magneton $\left(-\frac{he}{4\pi mc}\right)$ and the magnetic quantum number n_1, as it was expected.

It is noteworthy that the magnetic moment (7) arises in a certain way through the action of the field. In the absence of a magnetic field, the two states with n_1 equal in absolute value but of opposite signs, have the same energy; every linear combination of these two states is therefore a quantum state. Now it is easily seen from (4) that we can combine the two states in such a way that ψ becomes the product of $e^{2\pi i\frac{E}{h}t}$ and a real function of r, θ, ϕ (containing cos $n_1\phi$ or sin $n_1\phi$, as a factor). In this case the density of current j would vanish everywhere, and the magnetic moment would reduce to zero.

Psychical Phenomena and their Interpretation.

PUISQUE une controverse courtoise a pris place dans ce journal au sujet des recherches psychiques, il me sera permis de vous adresser quelques mots au sujet de mon opinion, motivée par de longues recherches (voir mon "Traité de Métapsychique," traduit en anglais, 1925, "Thirty Years of Psychical Research").

Il importe avant tout de distinguer les faits et les théories.

Pour les faits, ils ont été, à ce qu'il me semble, établis en toute évidence, et on ne peut attribuer ni à la fraude, ni à l'erreur, ni à l'illusion, la constatation de la plupart des phénomènes. Encore, à l'extrême rigueur peut-on soutenir que les faits d'ectoplasmie, de lumières, de télékinésie, demandent quelques confirmations nouvelles. Mais quant à la télépathie, la lucidité (second sight), la cryptesthésie, la prémonition, tous phénomènes n'impliquant pas d'action physique matérielle, il y a des témoignages si abondants et si précis qu'on ne peut se refuser à les admettre. A moins qu'on ne fasse fi de la méthode expérimentale. C'est se diminuer que de ne pas les reconnaître, suivant la forte parole d'Oliver Lodge

L'expérience est là pour établir, en toute certitude, qu'il y a, à la connaissance, d'autres voies que *les voies sensorielles habituelles*.

Et c'est tout ce que je puis admettre, jusqu'à présent, comme irrévocablement démontré. Mais c'est beaucoup déjà. L'existence de ce sixième sens est véritablement un monde nouveau qui s'ouvre à nous

L'intelligence est atteinte par des forces qui lui révèlent des faits que ni la vue, ni l'ouïe, ni le toucher ne peuvent lui faire connaître.

Alors, comme l'a dit mon illustre ami O. Lodge, deux hypothèses sont en présence. Ou bien ce sont des *esprits*, les âmes des défunts qui se manifestent à nous. Ou bien ce sont des *vibrations* (de nature inconnue) qui agissent sur notre organisme.

L'hypothèse des *esprits* est quelquefois très commode et s'adapte admirablement à certains faits ; mais elle soulève des objections formidables. Je ne la repousse nullement Pourtant je ne peux guère y croire et je ne la regarde que comme une hypothèse de travail.

L'hypothèse des *vibrations* (inconnues) me paraît préférable.

Après tout pourquoi ne pas supposer que la réalité émet des vibrations ? Ne voyons-nous pas des vibrations innombrables et puissantes, comme les ondes hertziennes et les ondes magnétiques, qui ne sont décelées que par des *détecteurs* spéciaux, et qui sans ces détecteurs, passeraient inaperçues ?

A vrai dire, je me préoccupe peu de ces hypothèses. Ce qui m'intéresse passionément, c'est la constatation des faits. Or il a été démontré par Crookes, Lodge, Myers, Sidgwick, et beaucoup d'autres, que l'intelligence humaine a parfois sur la réalité (très rarement, je le veux bien), des notions que les sens normaux ne peuvent lui donner. Tous ceux qui ont méthodiquement et sans préjugés étudié cette psychologie nouvelle ont été finalement forcés de l'admettre.

CHARLES RICHET.

The Fluorescence of Superheated Mercury Vapour.

IN a letter to NATURE (April 17, 1926, p. 555) I gave a short report of experiments on the fluorescence of mercury vapour. The conclusion arrived at was that the total intensity of the visible fluorescence in saturated mercury vapour, as well as that of different bands and lines in the visible and ultra-violet part of the spectrum, is, for a given exciting light, a function of the temperature only. These results are in disagreement with those of R. W. Wood and van der Lingen (*Proc. Roy. Soc.*, 99, 362, 1921, and *Astrophys. Jour.*, 54, 149, 1921). According to these authors the fluorescence can only be excited in freshly formed mercury vapour.

Further experiments, with various vessels containing mercury vapour and different kinds of exciting light, have fully confirmed my previous results. The fluorescence does not depend on whether the saturated mercury vapour is old or freshly formed.

These experiments suggest the possibility of exciting the fluorescence in the unsaturated mercury vapour. For this purpose some experiments have been carried out. An evacuated and sealed quartz tube was used containing an amount of mercury just sufficient to fill the vessel with saturated vapour at about 240° C The vessel was heated in an electric furnace closed with quartz windows. The temperature was measured by a thermometer and a thermopile fixed to the walls of the tube in two different places. The fluorescence excited by a condensed aluminium spark was observed visually and the spectrum taken with a quartz spectrograph. With rising temperature the minute mercury droplets in the vessel disappear gradually. At about 240° C. the last droplets vanish, the intensity of the fluorescence remaining unchanged. The intensity did not change either when the vessel was heated to 355° C. or kept for several hours at some constant temperatures above 300° C. The intensities of single bands and lines of the fluorescence spectrum remain likewise practically unchanged. The appearance of the spectrum is practically the same as in the case of saturated mercury vapour at about 240° C., and this proves that, above 240° C., the vapour was really unsaturated. Indeed, for the saturated mercury vapour the line 2537 Å.U. would disappear at about 260° C., and similarly the band situated on the long wave-length side of this line at about 280° C.

Previous experiments have shown that with changing vapour density (by varying the temperature of the saturated vapour) the fluorescence changes. In the present experiments the vapour density above 240° C. was constant and the fluorescence remained very nearly constant.

These results may be summed up by saying that for a given exciting light the fluorescence of the mercury vapour depends mainly on the density of the vapour. The age of the vapour is of no importance.

HENRYK NIEWODNICZAŃSKI.

Stefan Batory University,
Wilno, Poland, October 8.

Dr. Jeans and the 'Disease' of Life.

DR. JEANS can see after himself, I feel sure; and if he accepts the statement of the writer of the note on his address in NATURE of December 4, p. 812, that in his view life is "possibly merely a disease infesting the rubbish heap in the corner" of the universe, no other interpretation can live. But as a student of life I was on the point of writing to thank Dr. Jeans not only for his masterly address, but also, most of all, for his stately and hopeful close wherein no such opinion as the above was fathered by him. Readers of NATURE can turn to the original in the Supplement to the issue of December 4 and judge for themselves. Dr. Jeans put two interpretations, in two different ways, and his final brace were: Is life of the nature of a disease which affects matter in its old age, or is it the only reality, which creates, instead of being created by? The writer of the paragraph takes the first only and fixes it as Dr. Jeans's own view. Why?

It is probably of no importance to anybody but myself to say that I welcomed the second, and have long taken it, for the simple, and I suggest scientific, reason, among many others, that matter as I see it cannot apprehend or understand me, and that I at least am able to apprehend it. I do not see why the apprehender should be subordinate to the apprehended, which, whatever its volume, does not apprehend anything, not even itself.

J. J. ROBINSON.

Barnham, Sussex.

MR. ROBINSON'S letter reveals a misapprehension which might be shared by others, and should at once be removed. The note in question was not an independent report of Dr. Jeans's article. It was a comment on the article, published in the same issue of NATURE, and intended to be read in conjunction therewith. Its purpose was to direct attention to the Supplement and to indicate its general tendency. It was obviously impossible and undesirable to mention all Dr. Jeans's suggestions about life Those suggestions, indeed, were entirely secondary to the main thesis, which was that "the primary physical process of the universe is the conversion of matter into radiation." The possible view of life referred to in the note was selected because it threw the main thesis into the strongest relief. The selection carried no implication whatever that the view was the one favoured by Dr. Jeans or by modern scientific thought. As Mr. Robinson says: "readers can turn to the original and judge for themselves." In case Mr. Robinson imagines that there has been an insidious attempt to propagate materialism in the guise of science, let me say that personally I hold the idealistic view—so strongly, indeed, as to be able to contemplate the alternative with equanimity

It may possibly save further misunderstanding if this opportunity is taken of correcting two misprints in the original notes In line 3 of the first paragraph, "contributions" should be "constitution," and in line 4 of the second paragraph, "testing" should be "tasting."

THE WRITER OF THE NOTES.

The Action of Silica on Electrolytes.

THE importance of this subject in chemistry and pedology is my excuse for a further letter in reply to that of Prof. Mukherjee in NATURE of October 9 I could wish that he had told us more as to the method by which he demonstrates 'primary adsorption,' as until it is established—and this is the point of disagreement between us—it is scarcely worth while discussing its mechanism I have now tried so many variations of the experiment in attempting without success to obtain Prof. Mukherjee's results, that I am a little discouraged, and this the more because the magnitude of the effects described in successive communications has been greatly reduced. Thus the early statement that considerable quantities of acids could be adsorbed by silica was modified by his letter in NATURE (January 31, 1925) stating that the silica used contained alkali Again, in the issue of April 4, 1925, it was stated that 10 grams silica adsorbed 42 c.c of decinormal hydrochloric acid, *i.e.* 250×10^{-4} gram molecules of acid per gram molecule of silica. But in the letter under reply, this 250 has been reduced to 1.

In the letter of January 31, 1925, it is stated that the *p*H value hydrochloric acid rose from 3·4 to 4·6 by passage through air-dried silica We tried mixing pure silica with acid of this strength and found the *p*H values to be 3·45 before and 3·46 after the addition of the silica, results well within the experimental error.

It is most desirable that this question should be settled definitely. I would willingly try further direct experiments on mixing silica with acid if Prof Mukherjee would tell me the strengths and quantities which must be taken to be sure of obtaining his results. Meanwhile, I am of the opinion that silica does not adsorb acids A. F. JOSEPH.

Khartoum, November 3.

"Colloid Chemistry."

REFERRING to the review of vol. 1 of "Colloid Chemistry: Theoretical and Applied," which appeared in NATURE of October 23, p. 585, three references to electrodialysis are given in the book on p. 937, ultrafiltration dialysis is treated on p. 832, and electro-ultrafiltration on p. 834 *et seq.*, where a foot-note states that Dr P H. Prausnitz' paper on electro-osmosis (Graf Botha Schwerin, etc) will appear in vol. 3 It has so many descriptions of practical applications, that it justly belongs in the volume on technology. Diffusion is, furthermore, treated in the latter part of Svedberg's paper on centrifugal and diffusion methods for the study of dispersity and hydration in sols, and in papers by Liesegang, Bradford, and Holmes; and as Liesegang says, p. 784, "dialysis is practically the same thing as diffusion in jellies, only it permits us to recognise more distinctly the processes going on inside of the membrane" It would seem, then, that dialysis has more than "casual mention in two places," and that electrodialysis is not "neglected," even though neither is given elementary discussion JEROME ALEXANDER

50 East 41st Street,
New York City, November 15

THE process of dialysis is so widely used for the purification of colloids that one would expect to find some general treatment of it in a book of this size dealing with 'theory and *methods*' Diffusion into jellies, or without a septum, is not dialysis, nor are these methods used to any extent for the removal of non-colloidal substances. Similarly, the scattered references to electrodialysis are no substitute for a systematic treatment, nor is the promise of an article, in a future volume, on electro-osmosis, which is a different phenomenon P. C. L. THORNE

The 'Bleeding' of Trees through Injury.

MORE than two years ago there was a short correspondence in NATURE (113, pp. 492 and 604) on the 'bleeding' of trees in the spring through injury. The trees especially mentioned were the sycamore and birch. It may be of interest to record the fact that the common walnut (*Juglans regia*) may be included among the 'bleeders'—at any rate, the specimen I have had under observation behaved markedly so. Casually severing a twig of this tree in mid-spring, 1925, I was a little surprised to find that sap immediately exuded. On February 1 last this tree for certain reasons had reluctantly to be felled As the walnut is late in coming into leaf and adapted to a climate warmer than Cumberland can afford it, it was scarcely to be expected that so early in the year there would have been any exudation of sap My surprise therefore was great to find such an outflow, on the application of the crosscut-saw to the base of the trunk, as to cause the sawdust to become quite moist. In addition, as the woodmen lopped off the branches of the felled tree, sap issued so freely from the cut surfaces that it could have been collected.

The tree still further astonished me, for throughout the spring, summer, and early autumn, sap exuded copiously from the stump, making the soil around quite soppy. Micro-organisms of one kind or another revelled in the exudation and gave rise to a sickly stench. This during a spell of warm weather became so obnoxious that the surface of the stump had to be cleaned, dried, and disinfected. The outflow still continued after the treatment, and appears only to have stopped through the setting-in of the cold weather of October.

I have never noticed such a long-sustained bleeding in the case of the stools of the sycamore or birch These, however, usually sucker, and the sap may be utilised in this way, thus preventing any visible outflow. The walnut stump in question has shown no signs of sending up sucker-shoots.

JOHN PARKIN.

Blaithwaite, Wigton, Cumberland,
November 18.

Sir J. J. Thomson's Seventieth Birthday.

MESSAGES OF CONGRATULATION FROM ABROAD.

Prof. E P. ADAMS,
Princeton University, N.J.

IT is pleasant to have this opportunity to express the satisfaction I feel in having had the privilege of working in the Cavendish Laboratory under Sir Joseph Thomson. Modern physics owes much to his genius; in fact, modern physics is very largely built upon the work he himself did and the ideas he furnished to the workers in the Cavendish Laboratory Under his inspiring leadership the Cavendish Laboratory became the dominant centre for physical research, attracting students from all over the world who wished to come under his influence.

In addition to his stimulating interest in all the research carried out in the laboratory, Sir Joseph's lectures contributed much to the influence that the Cavendish Laboratory has exerted upon modern physics. His wonderful facility for making his hearers feel the reality of his point of view made his lectures full of suggestions for further work, and thus they carried out the principal object of lectures, which is to make the hearers think for themselves

Here in Princeton Sir Joseph is remembered with real affection. For in 1896, at the time of the sesquicentennial of the founding of the College, he came over and lectured on the results of his latest work. He aroused great interest in the new discoveries, and in his belief, rather startling at the time, that electrons are constituents of the chemical atoms. It was largely through his influence that Profs. J. H. Jeans and O. W. Richardson came to Princeton from Cambridge. Prof. Richardson was mainly responsible for building up at Princeton, in the Palmer Physical Laboratory, a school of physical research. This is only one illustration of many that might be given of the way in which the influence of Sir Joseph Thomson has spread out far beyond the Cavendish Laboratory.

Prof S. J. M. ALLEN,
University of Cincinnati.

If we say that a prophet receives more credit abroad than at home, it is equally true that in estimating the work of a great scientist the opinion of those outside his own country may be of more critical value than even that of his countrymen. This is especially true of Sir J J Thomson. To a reputation gained in his own country, and richly deserved, has been added the unstinted admiration of his co-workers in foreign lands, especially in the United States and Canada.

A fertile imagination, and true understanding of the nature of the problem, combined with the finest experimental skill, produced results of the greatest importance, reminding one of the immortal Faraday His method of subjecting a moving charge to the combined action of electrostatic and magnetic fields, with the resulting determination of e/m, for the electron, and later for the positive ray, made his fame secure, and paved the way for the recent brilliant work of Aston on the isotopes. When the time comes to erect his monument (may it be far distant), perhaps the noblest symbol that could be placed thereon would be "e/m."

The American, or Canadian, who has had the great pleasure and honour of meeting 'J. J.' as director of the Cavendish Laboratory, or as Master of Trinity, carries back with him the remembrance of a great scholar and genial host, and gains through this association a wealth of knowledge and suggestions that are invaluable to him in his future work.

Prof. NIELS BOHR, For Mem.R.S.,
University Institute of Theoretical Physics, Copenhagen.

It is with great pleasure that I accept the invitation of the editor of NATURE to take part in the universal celebration of the seventieth birthday of Sir J. J. Thomson, to whom every one interested in the problem of the constitution of the atom is so greatly indebted. Not to speak of the leading part he has taken in the discovery of the electron as a common constituent of all atoms, we owe to him an abundance of ideas which have proved fruitful in the attempts to develop a detailed theory of atomic constitution based on this fundamental discovery. At a time when even the existence of atoms was regarded by many prominent scientists with scepticism, Thomson had the courage to venture on an exploration of the inner world of the atom. Guided by his wonderful imagination and leaning on the new discoveries of the cathode rays, Röntgen rays and radioactivity, he opened up an unknown land to science. By following electrical particles and ether-waves on their way through atoms he obtained the first estimate of the number of electrons contained in an atom and of the forces by which they were bound, laying in this way the foundation of that elaborate structure which has been built up in recent years through the joint efforts of a large number of workers. We find in his famous attempt to account for the remarkable periodicity of the physical and chemical properties exhibited by the elements when arranged in the order of their atomic weights, the germ of the ideas characteristic of the modern interpretation of the periodic table. Indeed, it is difficult for scientists of the younger generation, who are working on the new land to which Thomson has opened the gates, fully to realise the magnitude of the task with which the pioneers were confronted.

M. LE DUC DE BROGLIE,
Membre de l'Académie des Sciences, Paris.

Il suffit d'un coup d'œil jeté sur l'histoire scientifique des quarante dernières années pour voir que le développement de la physique moderne, c'est-à-dire de la théorie électronique de la matière a pris naissance quand on a compris en quoi consistait le passage de l'électricité à travers les gaz.

C'est la notion d'ionisation qui a permis d'étudier les rayons X et de découvrir la radioactivité comme c'est elle également qui a mis sur la voie des représentations actuelles de l'atome, si profondes, si fécondes déjà et si pleines de promesses pour l'avenir.

Or c'est à Sir Joseph Thomson et à ses élèves qu'est due presque entièrement l'interprétation de l'ionisation des gaz, expliquée pas à pas par les physiciens de Cambridge et si objectivement mise en évidence par l'un d'eux, le professeur C. T. R. Wilson

Aujourd'hui encore le premier livre à mettre entre les mains de celui qui veut s'initier à la physique du vingtième siècle est la "conductibilité électrique des gaz" écrit par le chef et l'animateur du Cavendish Laboratory. Il y a peu de temps, en en voyant une récente édition j'admirais combien la plus ancienne avait été merveilleusement composée pour avoir été si peu modifiée par les travaux des vingt-cinq années les plus actives de la physique électronique. Sir Joseph Thomson avait tracé un cadre si parfait des nouvelles perspectives de la science que les progrès ultérieurs de celle-ci semblent n'avoir été que le développement et l'achèvement des divers chapitres de son ouvrage. La part personnelle prise par l'ancien chef du Cavendish Laboratory, tant au point de vue théorique qu'expérimental dans toute cette partie de la physique, et le couronnement plus récemment apporté par la découverte fondamentale des spectres de masse des corps simples lui vaudront la gloire difficile d'inscrire sans crainte son nom à côté de celui de ses illustres prédécesseurs.

Le titre auquel a droit le très grand savant que l'on honore aujourd'hui est peut-être le plus beau que puisse ambitionner un homme de science et de génie: il a été le guide et le flambeau de toute une génération de physiciens qui portent aujourd'hui les noms les plus illustres de la science actuelle et son influence se fait sentir maintenant sur les élèves de ses élèves.

Toutes les nations du monde envient le Cavendish Laboratory pour son passé comme pour son présent.

Prof. D. F. COMSTOCK,

Massachusetts Institute of Technology, Boston.

On the occasion of Sir Joseph Thomson's seventieth birthday, will you allow one of his old students, who long since strayed from physics into the field of engineering research, to express his congratulations and to acknowledge gratefully a many-sided debt to him?

I went to the Cavendish for the purpose of absorbing, if possible, a little of his vision, a little of his way of looking at problems which were still nebulous; and through his kindly patience with the immaturity of a young student, I absorbed as much of this subtle influence as my capacity would allow. Whatever originality I may have shown through the intervening years is traceable in no small part either to his direct influence at that time or to his writings before or since.

I know that many, who are not primarily physicists, have benefited by this extraordinary power of Sir Joseph's to stimulate the originality of others, and because of this characteristic of his genius, his influence has spread far beyond the confines of pure physics.

I know that I am expressing the feeling of industrial research workers in general when I gratefully acknowledge our obligation to Sir Joseph not only for the new truths of Nature which his researches have uncovered, but also for the subtle stimulus which comes even from his writings and makes research work in any field happier and more successful.

Mme. CURIE,

Radium Institute, Paris.

Sur la demande de M. l'Éditeur de NATURE, il m'est agréable de m'associer à l'hommage rendu par le monde scientifique à M. le Professeur J. J. Thomson dont j'apprécie hautement l'œuvre, aussi bien pour la profondeur et l'originalité des vues théoriques que pour l'important ensemble de recherches expérimentales. Sans essayer d'envisager toute la variété des travaux de Sir J. J. Thomson, je désire rappeler que nous lui devons un grand nombre de résultats fondamentaux relatifs à l'étude des particules chargées, molécules, atomes et électrons. Parmi ces résultats, nous trouvons les premières déterminations de la charge élémentaire et du rapport de la charge à la masse pour l'électron, ainsi que la première notion de la masse électromagnétique. Non moins riches en conséquences sont les recherches de Sir J. J. Thomson sur les rayons positifs et l'interprétation si sûre qu'il en a donnée, conduisant à une nouvelle méthode d'analyse chimique qui est applicable à de très petites quantités de matière et dont on connaît le succès dans la généralisation de la notion de l'isotopie.

Le nom de Sir J. J. Thomson est souvent prononcé dans les laboratoires de physique, plus particulièrement dans ceux qui se consacrent à l'étude des particules portant une charge électrique et à celle de leur mouvement. C'est là un des problèmes qu'on aborde fréquemment dans les laboratoires destinés aux recherches sur les phénomènes radio-actifs—et c'est à ce titre que j'ai plaisir à exprimer à Sir J. J Thomson ma gratitude pour l'importante contribution scientifique représentée par ses travaux personnels ainsi que par ceux qu'il a inspirés et dirigés.

Prof. GEORGE E. HALE, For Mem.R.S,

Mount Wilson Observatory, Pasadena, California.

I have always felt the exceptional stimulus of two great English laboratories, which for generations have maintained positions of leadership because of the men who have worked in them. The Royal Institution, dating from the time of Rumford and Young, is rich in traditions for the astronomer scarcely less than for the physicist. But in these days, when cosmic experiments are so frequently necessary to test the tenets of relativity or the ultimate consequences of theories of matter, we who devote ourselves to astrophysical research perhaps feel an even greater indebtedness to the Cavendish Laboratory. What a lineage of directors it holds before us—Maxwell, Rayleigh, Thomson, Rutherford! Among these we must attribute chiefly to Thomson its advance to an international position as a centre of research.

I remember with special pleasure my frequent visits to Cambridge, in peace and war, and the never-failing inspiration of my talks with Sir Joseph. It has been a great privilege to watch the growth of his ideas and to see the vacuum tube transformed under his hand from a coiled spectacle for the curious to a powerful instrument of research. He was among the first to explain the presence of charged particles in the sun, and in many other ways he has placed students of astrophysics under obligation. I am personally indebted to his writings for more than one basic suggestion, and I appreciate no less his encouragement during my efforts to extend the use of laboratory methods in astronomical observatories. I am, therefore, pleased to be permitted to join in warm congratulations to Sir Joseph and the Cavendish Laboratory on the occasion of the celebration of his seventieth birthday. I can offer no better wish than that the splendid successes of the past may continue through a long and happy future.

Prof. CHAS. T. KNIPP,

University of Illinois, Urbana.

Sir Joseph Thomson's influence reached the central of the United States during the early 'eighties. I remember distinctly, a decade later, as a pupil in a small county seat high school in north-western Ohio, that our teacher in 'natural philosophy' directed the attention of the class to a possible new theory of the structure of matter proposed by Prof. J. J. Thomson, of the Cavendish Laboratory of physics at Cambridge, England. This reference was to his vortex theory. The story caught the attention of the class, for we all had seen the wonderful smoke rings shoot up from the old style funnel-shaped locomotive stacks. From that time on any reference in the newspapers to Prof Thomson was eagerly sought, and almost unconsciously I became a great admirer of his ability.

A few years later while in the university, I found this same feeling of respect and admiration shared by those studying in the domains of physics and chemistry. Theories advanced by Thomson formed our topics for discussions. His discovery that the electron carries a negative charge and is a constituent of all matter, his identification of the Edison effect as due to electrons, and his later measurement of the charge and mass of the electron, were accomplishments that promptly received the commendation of American physicists and chemists. He was the leader during this the electron period. Afterwards his great contribution on the study of the properties of the elements by positive ray analysis attracted wide attention in America. Here again he was the pioneer worker and blazed the way for entrance upon the positive electricity or proton period, as it may now be called.

Nor are we in the States unmindful of Sir Joseph Thomson's brilliant conception of atomic structure, in which the various elements are represented as combinations of negative electrons and positive charges arranged as miniature solar systems—a conception that will always stand for the guidance of research on this fundamental problem.

Beginning with 1890, and continuing up to the present, the writings of no one person have had a greater influence upon the research activities in physics in American universities than those of Sir Joseph Thomson. That this statement is correct is attested by the large number of students from there that have sought out the Cavendish Laboratory for the doing of productive research. Personally, it is this high regard for Sir Joseph as a scholar, investigator, and as a gentleman, that impelled my second visit (the present one) to the Cavendish Laboratory, to engage in research and to lay claim, as it were, to his terse and illuminating criticisms and valuable suggestions.

Research in physics and chemistry in the United States owes a debt of gratitude to Sir Joseph Thomson for his marvellous record of nearly fifty years of uninterrupted original contributions. As one of many from across the Atlantic, I humbly add the foregoing as a message of appreciation of the accomplishments of an active and productive personality.

Prof. ALOIS F. KOVARIK,

Yale University, New Haven, Connecticut.

During the past as well as during the present generation, the Cavendish Laboratory has been the Mecca for physicists from all parts of the world, and we Americans owe a debt of gratitude to it for aiding and developing the spirit of research in physics in America. There is scarcely a physicist in America who has not been a pupil of Sir Joseph or else a pupil of one of his pupils. In the case of the latter, the enthusiasm for research and the high esteem for the Master came not only by reflection from those more fortunate ones who had been with the Master himself, but even in some cases with added force, for the powers inherent in his pupils were released by virtue of their contact with him. To these men Sir Joseph was made known not only as a physicist who opened the fields of electronics and of atomic structure, but also as a most congenial and sympathetic man. To them also he soon became simply 'J. J.' They seemed to learn to know him intimately even before meeting him personally on his several welcome visits to America.

Those of us who have been more fortunate and to be privileged to associate with him at one time or another, have had an increasing esteem for him not only because of the great scientific achievements which his mind made possible, but also for those things which a man likes to find in another man. Not only did he show interest in one's scientific work, but also he always showed human interest in the man himself, his friends, and the institutions with which he was connected. We all love his characteristic smile, and every one of us felt a certain pleasure within ourselves on hearing a footstep that every Cavendish man recognises as solely 'J. J.'s.'

It was my good fortune to have been a pupil of two of his pupils and to have experienced the delights from such associations, but at more recent time I had the privilege to be associated with him in the Cavendish and in Trinity—as a guest in both—and it is a pleasure to admit that my love for him, for his human and personal qualities, causes no less pleasure to me than my great admiration for his genius as a physicist.

Prof. PAUL LANGEVIN,

Collège de France, Paris.

J'ai eu la bonne fortune de commencer ma carrière scientifique par un séjour d'une année au Cavendish Laboratory, dans la période où, sous l'impulsion de Sir Joseph Thomson, immédiatement après la découverte des rayons de Rontgen et de la radioactivité, se constituait cette École de Cambridge dont l'influence a été si grande depuis trente ans sur le développement de la physique moderne.

Le plus charmant souvenir m'est resté de cette époque déjà lointaine depuis laquelle l'importance et la réputation du laboratoire n'ont cessé de grandir. Nous étions une quinzaine de jeunes gens venus de pays bien différents pour mettre en commun l'enthousiasme que leur inspirait la science nouvelle et réunis dans une commune admiration pour le jeune maître dont le rayonnement les avait attirés.

Il y avait là Brown, Child, McClelland, Henderson, Henry, Richardson, Rutherford, Shakespear, Townsend, Vincent, Wade, C T. R. Wilson, H. A. Wilson, Zeleny Nous avons eu récemment à déplorer la mort prématurée de McClelland ; celui qui est maintenant Sir Ernest Rutherford est venu diriger un Cavendish Laboratory singulièrement agrandi ; les autres sont dispersés un peu partout dans le monde. J'espère qu'un bon nombre d'entre eux se retrouveront la semaine prochaine à Cambridge pour évoquer des souvenirs et reprendre, autour du maître resté si actif malgré les années, les conversations anciennes qui s'échangeaient à l'heure du thé, dans son cabinet où nous nous réunissions après sa visite quotidienne à chacun de nous

De cette époque datent les premiers travaux de Sir Joseph Thomson sur les rayons cathodiques et la décharge disruptive. Il commençait cette admirable série d'expériences qui devait aboutir à la découverte de l'électron négatif et à la création de la méthode si féconde des spectres de masse.

Du côté théorique comme du côté expérimental, l'œuvre si personnelle de Sir Joseph n'a fait que grandir en même temps que de plus en plus nombreux ont été ceux qui, chaque année, sont venus s'inspirer de sa parole et de son exemple pour répandre ensuite sa pensée et garder entre eux des liens précieux pour eux-mêmes et pour l'avenir de la science.

Les témoignages de reconnaissance et d'admiration qui viendront vers lui à l'occasion de son soixante-dixième anniversaire montreront à Sir Joseph Thomson combien son action a été grande et combien sont fortes les affections qu'il a su rassembler autour du laboratoire illustré par lui.

Prof. THEODORE LYMAN,

Jefferson Physical Laboratory, Harvard University, Cambridge, Mass.

When I entered the Cavendish Laboratory as a graduate student in the fall of 1901, I found myself in an atmosphere of a stimulating quality which I have never seen equalled in any other place Not infrequently the influence of a great man upon his time is indirect, but Prof. Thomson not only illuminated the scientific world of the period of which I speak, but also managed to carry his students with him into his own realm of intellectual enthusiasm.

To the majority of us the prosecution of research is a laborious business ; the road is long and steep, blind byways beset us, the perversity of inanimate objects foils us. But those of us who know Sir Joseph Thomson and appreciate his genius are in a position to realise that to one whose mind is attuned to Nature the path of knowledge is neither tortuous nor laborious. The experience gained at the Cavendish remains, even after the lapse of a quarter of a century, a happy memory and a source of lasting inspiration.

Prof A A. MICHELSON, For Mem.R S.,

Ryerson Physical Laboratory, University of Chicago

It gives me sincere pleasure to add to the others an expression of my high appreciation of the magnificent work of Sir Joseph Thomson and the influence it has had on the whole field of electronics and radioactivity. No other discovery has so profoundly altered our notions of the ultimate structure of matter. I welcome the opportunity of expressing my most cordial congratulations and best wishes for the continuation of his activities for many decades to come

Prof. ROBERT A. MILLIKAN,

California Institute of Technology, Pasadena

It is not merely the group of erstwhile workers in the Cavendish Laboratory who owe to Sir Joseph Thomson the chief inspiration of their scientific careers. I speak for many who have never been students there when I say that no man living has exerted so large an influence upon my own activity in physics as has Sir Joseph It was his writing which stimulated my entrance in 1903 into the domain of photoelectric research, a domain which has been one of my chief interests ever since. It was he who inspired me so early as 1905 to try to pull electrons out of cold metals by fields alone, a research which led through all the mazes of high vacuum technique, and yielded results of importance in the direction aimed at only after ten years of effort. It was he whom I followed in making cloud experiments when I first observed, and worked with, isolated electrons. It was he who directed the thought of all of us in seeking to build atomic models based on electron configuration It was he who made the first analysis of space charge effects, who pointed out the existence of mass as a function of electric charge and showed how to compute its value. In a word, it was he who, more than any other one individual, was responsible for formulating, and gaining general acceptance for, the theory of the electronic construction of matter—an idea that is probably to exert larger influence upon the destinies of the race than any other idea which has appeared since Galileo's time.

Prof. VLAD. NOVÁK,

Technical High School, Brno.

Forty years ago little was known of British methods in physics and other natural sciences in the historic lands of Czechoslovakia Our instructors, having been taught and trained in German schools, followed German methods. The German University of Prague was divided into German and Bohemian schools in sections in 1882. The natural sciences were studied in the Bohemian Philosophical Faculty of the Charles and Ferdinand University of Prague in the first ten

University Tutorial Press

SELECTED SCIENCE TEXT-BOOKS

Agriculture.

Chemistry for Agricultural Students. By R. H. ADIE, M.A., B.Sc., Lecturer in Physics and Chemistry, School of Agriculture, Cambridge; Examiner in Agricultural Science for the Cambridge School Certificate Examination. **5s. 6d.**

"The student of agriculture who is desirous of mastering the fundamentals of Chemistry and Physics will find no better help than this book."—*Chemical Trade Journal.*

Biology.

Text-book of Botany. By J. M. LOWSON, M.A., B.Sc., F.L.S. *Sixth Edition.* **9s. 6d.**

This text-book gives in a clear and simple manner a general survey of the science, including Angiosperms, Gymnosperms, Vascular Cryptogams, and Lower Cryptogams, with a chapter on Evolution and Genetics.

"It represents the nearest approach to the ideal botanical text-book that has yet been produced."—*Pharmaceutical Journal.*

Text-Book of Zoology. By H. G. WELLS, B.Sc., and A. M. DAVIES, D.Sc. Revised by J. T. CUNNINGHAM, M.A. *Sixth Edition.* **8s. 6d.**

A careful work on Vertebrates and Invertebrates suitable for school and college use.

"Admirably adapted for its purpose."—*Cambridge Review.*

Chemistry.

The Tutorial Chemistry. By G. H. BAILEY, D.Sc., Ph.D., late Lecturer in Chemistry at the Victoria University of Manchester. Edited by WILLIAM BRIGGS, LL.D., M.A., B.Sc., F.C.S.

PART I. Non-Metals. *Fourth Edition.* **5s.**

Section I. gives the student a thorough insight into the nature of the problems with which Chemistry deals, and a clear idea of the broad lines of chemical theory.

Section II. contains a systematic treatment of the non-metals, with suitable illustrative experiments.

PART II. Metals and Physical Chemistry. *Sixth Edition.* **7s. 6d.**

This volume contains an account of Physical Chemistry and of the Chemistry of the Metals.

"The leading truths and laws of chemistry are here expounded in a most masterly manner."—*Chemical News.*

Principal—GEO. PATCHIN, A.R.S.M., M.I.M.M.

ALTERNATING CURRENTS AND ELECTRICAL OSCILLATIONS

By D. OWEN, B.A., D.Sc., F.Inst.P.

A course of 10 lectures accompanied by practical demonstrations, intended for post-graduate students and those otherwise qualified to pursue this branch of electrical science and its applications in wireless telegraphy and telephony.

Tuesdays, from 7 to 8.30 P.M., commencing January 11, 1927.

ELECTROLYTIC ANALYSIS

By H. J. S. SAND, D.Sc., Ph.D., F.I.C.

A course of 5 lectures and practical work intended for analysts and others. It is also suitable as a revision class in electrochemistry for students preparing for the examinations of the Institute of Chemistry and London University.

Thursdays, from 7 to 9 P.M., commencing January 13, 1927.

ADVANCED COLLOID CHEMISTRY

By E. HATSCHEK, F.Inst.P.

A course of 10 lectures and demonstrations with the object of giving to those possessing a general knowledge of colloid chemistry the mathematical theory and a detailed account of a number of important aspects of the subject.

Tuesdays, from 8.15 to 9.15 P.M., commencing January 18, 1927.

MODERN DEVELOPMENTS RELATING TO FUEL

A special course of about 8 lectures dealing with the latest developments in connection with coal mining, carbonisation and powdered and liquid fuel, will be given by recognised experts on:

Monday evenings, 6 to 7 P.M., commencing January 24, 1927, at 6 P.M.

Details of the above courses may be had upon application to the PRINCIPAL.

CHEMICAL AND TECHNICAL BOOKS

We carry a very large stock both Second-hand and New in all departments of Technology, and can quote the best terms.

FOYLES, 121 Charing Cross Road, London.

MACMILLAN'S NEW AND RECENT BOOKS.

CATALYSIS IN THEORY AND PRACTICE. By ERIC K. RIDEAL, Owen Jones Lecturer on Physical Chemistry, Cambridge University, England, and HUGH S. TAYLOR, Professor of Physical Chemistry, Princeton University, U.S.A. Second Edition. Illustrated. 8vo. 20s. net.

Progress in catalytic studies since this volume was first published has necessitated a complete revision of the text and the addition of several new chapters in this second edition.

CRYSTALLINE FORM AND CHEMICAL CONSTITUTION. By A. E. H. TUTTON, D.Sc., M.A.(Oxon), F.R.S., Past President of the Mineralogical Society, London; Author of "Crystallography and Practical Crystal Measurement." With 72 Illustrations. 8vo. 10s. 6d. net.

THE MINERALOGICAL MAGAZINE —"The book is well printed and illustrated, and it gives a very clear and readable account of the subject It should be seen by all students of chemistry as well as those of crystallography."

REALITY: A NEW CORRELATION OF SCIENCE AND RELIGION. By CANON BURNETT HILLMAN STREETER. 8s. 6d. net.

THE SUNDAY TIMES.—"This is an altogether admirable book on a subject which is attracting more and more attention at the present day It is hardly too much to say that it is the best book of its kind that has been published in recent years."

MIND IN EVOLUTION. By L. T. HOBHOUSE, Hon.D.Lit., Hon.LL.D., F.B.A., Martin White Professor of Sociology in the University of London. Third Edition. 8vo. 12s. 6d. net.

Appendices on the German "Configuration Theory" and on the problem of "Instinct in Man" have been added to this new edition.

HOLISM AND EVOLUTION. By GENERAL THE RIGHT HON. J. C. SMUTS. 8vo. 18s. net.

THE MORNING POST.—"General Smuts has admittedly confined himself to an introductory sketch in the present book, but he has suggested a valuable line of inquiry which is in harmony with important currents of scientific and philosophic thought of to-day."

NATURAL MAN: A RECORD FROM BORNEO. By CHARLES HOSE, Hon. Sc.D., formerly Divisional Resident, and member of the Supreme Council of Sarawak. With a Preface by PROF. G. ELLIOT SMITH, F.R.S. With Illustrations and Map Super Royal 8vo. 30s. net.

THE SATURDAY REVIEW.—"One of the most attractive features of a fascinating book are the plates. . . . It is superfluous to congratulate Dr. Hose on his latest achievement, for it is only what was expected of him."

A SHORT HISTORY OF MARRIAGE. By EDWARD WESTERMARCK, Ph.D., Author of "Ritual and Belief in Morocco," etc. 8vo. 10s. 6d. net.

THE NEW STATESMAN.—"Those who had neither the leisure nor the courage to face the three volumes of Dr. Westermarck's monumental *History of Human Marriage* should welcome this shorter monograph."

PROJECTIVE GEOMETRY. By CLEMENT V. DURELL, M.A., Senior Mathematical Master at Winchester College. Crown 8vo. 7s. 6d.

THE MATHEMATICAL GAZETTE, in a review of the volume of which this is an abridged form, says. "The author possesses a thorough grasp of his subject, and the power of presenting it in an eminently attractive manner. . . . The book is a notable and most attractive addition to the literature of the subject."

ANSWERS, HINTS AND SOLUTIONS OF THE EXERCISES IN SAME. Crown 8vo. Limp Cloth. 2s. 6d.

HIGHER MATHEMATICS FOR STUDENTS OF ENGINEERING AND SCIENCE. By FREDERICK G. W. BROWN, M.Sc.(London), F.C.P, Senior Mathematical Master, West Ham Secondary School. Crown 8vo. 10s.

AN ATLAS OF HUMAN ANATOMY FOR STUDENTS AND PHYSICIANS. By CARL TOLDT, M.D., assisted by PROFESSOR A. D. ROSA, M.D. Adapted to English and American and International Terminology by M. EDEN PAUL, M.D.Brux., M.R.C.S., L.R.C.P. Revised Edition. With 1505 Illustrations. 2 vols. Demy 4to. 42s. net.

Supplement to NATURE

No. 2981 DECEMBER 18, 1926

Retrospect.

By Sir J. J. Thomson, O.M., F.R.S.

THE editor has asked me for some personal recollections of the Cavendish Laboratory, and I feel it would be churlish to refuse, though it is difficult to condense the happenings of more than forty years into a reasonable space, and still more difficult to avoid being egotistical. My connexion with the laboratory did not begin until I took my degree in January 1880. Before coming up to Cambridge I had, at the Owens College, under the inspiration of Balfour Stewart, become keenly interested in experimental physics and had done a small piece of research which was published just fifty years ago in the *Proceedings of the Royal Society*. The work for the Mathematical Tripos was, however, too heavy to leave time for experiments in the laboratory. As soon as the Tripos was over I started work at the laboratory, where Lord Rayleigh had just been made professor, and at his suggestion I began using a method, which he designed, an investigation on the ratio of the electrostatic to the electromagnetic unit of electricity. I made also theoretical investigations on applications of generalised dynamics to physics and chemistry, on vortex motion, and on the effects produced by the motion of electrical charges. There was great activity at the laboratory during Lord Rayleigh's time; Glazebrook and Shaw organised courses of instruction in practical physics; and Mrs. Sidgwick, Schuster, Glazebrook, Shaw, Poynting, E. B. Sargant, McConnel, J. A. Fleming, Hart, Miss Harland, and J. H. Middleton were working at various researches.

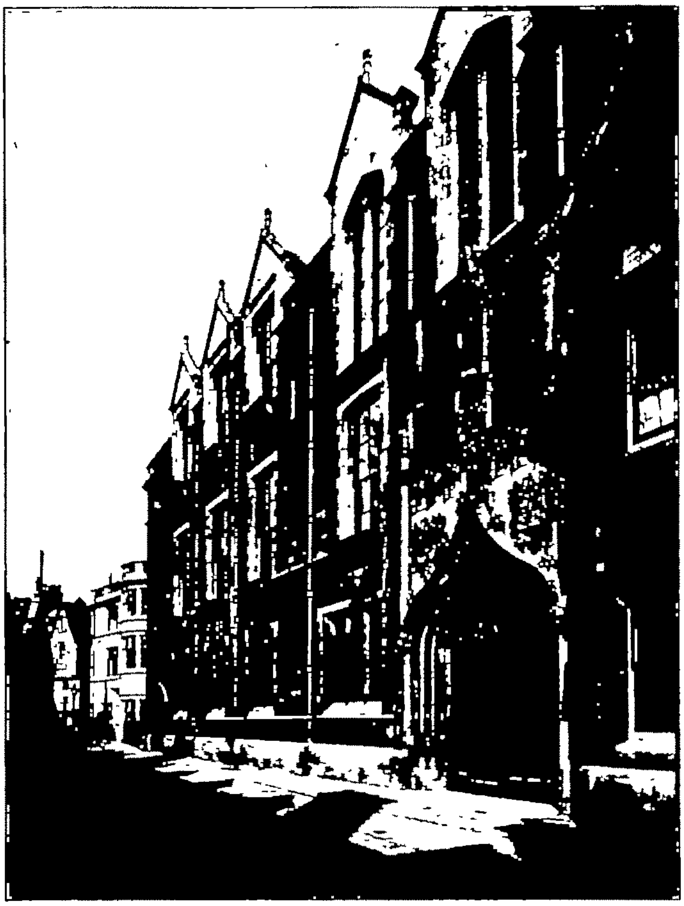

FIG. 1.—General view of part of the Cavendish Laboratory from Free School Lane. The new Rayleigh Wing is seen in the distance.

At the end of 1884, Lord Rayleigh resigned the professorship, and to my great surprise, and I think to that of the rest of the University, I was appointed to succeed him. I heard at the time that one well-known college tutor had expressed the opinion that things had come to a pretty pass in the University when mere boys were made professors. My want of experience was made less harmful than it might have been by the kindness of Glazebrook and Shaw, who continued to take charge of the teaching in practical physics. Immediately after my election to the professorship I began, in collaboration with my old friend Richard Threlfall, one of the most skilful experimenters I have ever met, some experiments on the passage of electricity through gases, and since then I think there has never been a time at which I have not had some experiments in hand on this subject. I had come to the conclusion that whenever a gas conducts electricity, some of its molecules must split up and that it is these particles which carry the electricity. My idea at that time was that the molecule was split up into two atoms, one of which was positively, the other negatively, electrified, and my first experiments were intended to test this idea. It was not until the beginning of 1897 that I discovered that the decomposition of the molecules was of quite a different type from ordinary atomic dissociation. I found then that one of the bodies into which the molecules split up, the one carrying the negative charge, is something totally different from an atom, and has a mass less than a thousandth part of the smallest atom known. I was fortunate enough soon after becoming professor to be able to persuade H. F. Newall, now professor of astrophysics in the University, to come and help in the work of the laboratory, and for some time we worked in collaboration on various researches.

In 1887 a great scientific discovery was made which appealed especially to every one connected with the laboratory: I allude to the detection by Hertz of electrical waves. The existence of these waves is a necessary consequence of Maxwell's electromagnetic theory, but though numerous attempts to detect them had been made, some of them at the Cavendish Laboratory, they had all failed owing to the want of a sufficiently delicate instrument to detect their presence. Hertz, by observing the variations in intensity of the minute sparks which pass between conductors near together when electrical waves pass over them, was able to demonstrate the existence of these waves. The younger school of mathematical physicists at Cambridge, who had been brought up on Maxwell's "Electricity and Magnetism," received Hertz's discovery with the welcome which might be expected from those who found their most cherished convictions confirmed by a series of most beautiful experiments; it established instead of revolutionising our ideas. I well remember the enthusiasm of the undergraduates when I repeated Hertz's experiments in my lectures on electricity and magnetism in 1888. The enthusiasm spread to all the workers in the laboratory, and soon experiments on electric waves were going on all over the building.

Among the Cambridge men doing researches in the laboratory up to 1895—the year of the admission of research students—were, in addition to those already mentioned, Cassie; W. H. Bragg for a short time; Wilberforce, who was a demonstrator until he became professor of physics at Liverpool; Chree, who became superintendent of Kew Observatory; H. L. Callendar, now professor at the Imperial College of Science, who was elected to a fellowship at Trinity College for natural science after having taken first classes in both classics and mathematics, and began at the Cavendish Laboratory those researches on the effect of temperature on the resistance of metals which have revolutionised thermometry; T. C. Fitzpatrick, now president of Queen's College, who for more than twenty years had the charge of the classes to medical students, and in 1904 presented to the laboratory apparatus for producing liquid air—this gave us the means of producing high vacua, and without it many of the most important researches would have been impossible; G. F. C. Searle, to whose devotion and enthusiasm the laboratory owes more than I can express, and whose fertility and ingenuity in designing instructive and ingenious experiments for demonstration in practical physics remains quite unabated; W. C. D. Whetham, later a tutor of Trinity College, who worked at problems on the properties of solution; Sidney Skinner, now principal of the South-Western Polytechnic, who was for many years a demonstrator; J. W. Capstick, until he became junior bursar at Trinity College; J. B. Peace; Alexander Anderson; C. E. Ashford; Miss Freund, and Miss Klaassen. Among our guests from other universities were Sir Oliver Lodge, who worked for one long vacation in collaboration with Glazebrook on the determination of *v*; A. M. Worthington, who made an important investigation on the tensile strength of liquids; while H. F. Reid, of Johns Hopkins, Baltimore, Olearski, from Lemberg, and Natanson, from Cracow, were the precursors of the many distinguished teachers from foreign universities who have honoured us by working in the laboratory.

The year 1895 was an epoch in the history of the laboratory, as then the University decided to admit as research students graduates of other universities whether at home or abroad, and in certain cases students who are not graduates, provided they satisfy the authorities that they are qualified to do research. In October 1895, the first two research students—Rutherford, from New Zealand, and Townsend from Trinity College, Dublin—arrived within a few hours of each other. Did a new system ever have such a good beginning? Rutherford began by working at wireless telegraphy, using a detector which he had invented before leaving New Zealand: it was so successful that the laboratory held for a time the record for long-distance telegraphy, communications being established between the laboratory and the observatory nearly two miles away. Townsend made a very important investigation on the magnetic properties of iron when in chemical combination.

It was fortunate that the new regulations, which brought to the laboratory a large influx of students bent upon research, came just at the time when the discovery of the Röntgen rays gave us a very powerful method of investigating the mechanism of the conduction of electricity through gases. A great many researches had already been made in the laboratory on this subject, and our studies had shown the fundamental importance of certain investigations which were almost impracticable with the means then at our command. The Röntgen rays gave us a means more amenable to purposes of investigation than those hitherto available and made many investigations possible which had before been hopelessly difficult. The investigation of the electrical properties of gases under the action of Röntgen rays soon engaged the attention of many workers in the laboratory. Rutherford, Townsend, McClelland, Langevin, who had come to us from Paris, were all hard at work. C. T. R. Wilson began those researches on condensation which, *ohne Rast ohne Hast,* he has pursued ever since, obtaining results of continually increasing importance for the development of modern physics.

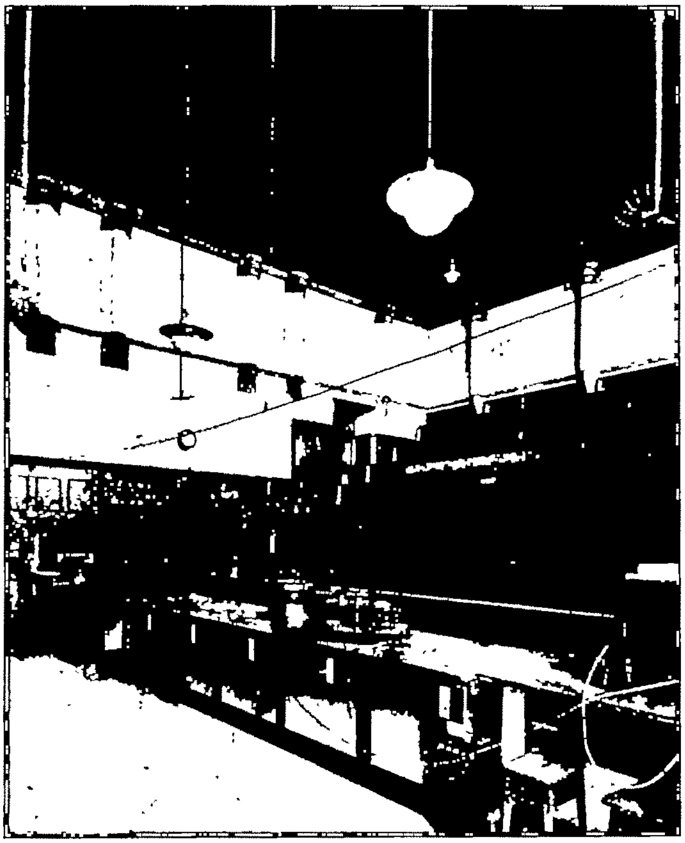

Fig. 2.—Lecture room of the Cavendish Laboratory, designed by Clerk Maxwell. Reproduced from a photograph kindly supplied by Mr. Rollo Appleyard, International Standard Electric Corporation.

It is not, I think, claiming too much to say that these researches played a great part in establishing the theory now universally accepted that the electricity is carried through gases by particles charged with electricity. The properties of these particles were studied in great detail at the laboratory, and they seemed to indicate that they were at least as large as the atoms of the gas in which they were produced. Some experiments which I made at the beginning of 1897 led, however, to the discovery of particles of quite a different order of magnitude. The cathode rays, which proceed from the cathode when an electrical discharge passes through a gas at low pressure, were discovered by Hittorf, and many experiments had been made on them by Goldstein, Varley, and Crookes.

Two widely different views were, however, held as to the nature of these rays. The majority of the German physicists maintained that they were analogous to electric waves, and urged in support that they could pass through thin sheets of metal. The English physicists held that they were charged particles, and brought forward the argument that when the rays entered an insulated vessel they communicated to it a charge of negative electricity. I had for a long time been convinced that these rays were charged particles, but it was some time before I had any suspicion that they were anything but charged atoms. My first doubts as to this being the case arose when I measured the deflexions of the rays by a magnet, for these were far greater than I could account for on any hypothesis that seemed at all reasonable if the particles had a mass approaching even that of the hydrogen atom—the smallest mass then known. I made a series of measurements of the velocity of these particles and the ratio of their mass to their charge. These all showed that the ratio of mass to charge for the cathode particles was less than one-thousandth part of the same ratio for the atom of hydrogen and its electrolytic charge. Thus, unless the electric charge on the cathode ray were at least a thousand-fold that on the electrolytic ion, the mass of the cathode ray particles must be less than that of an atom of hydrogen. Methods were devised by which the charge on these particles could be measured, and it was found to be the same as the electrolytic charge. I could see no escape from the conclusion that in the cathode rays there were particles far more minute than any hitherto recognised. I think the first announcement of this result was made at a Friday evening meeting of the Royal Institution on April 30, 1897.

Later investigations have shown that these particles—the electrons as they are now called—are always of the same kind and form a part of every kind of matter. The number of electrons in the atoms of the different elements was determined by applying a theory of the scattering of these rays by electrons which I had worked out from the valuable measurements by Barkla on the amount of radiation scattered by different gases, and it was found that this number was proportional to the atomic weight of the element and was of the same order as that number This led me to construct a theory of the structure of the atom which had special reference to the chemical properties of the element, for it was shown that such a structure would give a variation of the chemical properties with the atomic weight quite similar to that expressed by Mendeléef's law. Another excursion I made into chemistry was to use the magnetic and electric deflexions of the positive rays to determine the chemical composition of the gas in which they were generated. It proved a useful method, and Dr. Aston has modified and improved it, so that it is now one of extraordinary delicacy and accuracy.

The number of those engaged in research grew very rapidly, and for many years before the War there were always thirty or more researches going on in the laboratory. This put a great strain upon the apparatus and upon the workshop. We have been very fortunate in our chief assistants, and the laboratory owes much to Mr. Sinclair, Mr. Bartlett, and Mr. Pye, and especially to Mr. Lincoln, who has been chief assistant since 1899. Personally, I am greatly indebted to the skill and care of Mr. E. Everett, who has been my private assistant for nearly forty years, and has given me most valuable and able assistance in my investigations.

It is impossible here to mention individually the research workers between 1895 and the beginning of the War: their number is too great. Suffice it to say that three of them have gained the Nobel prize, twenty-two have been elected fellows of the Royal Society, and more than fifty have become university professors of physics. When the War began the usual work of the laboratory stopped. The research workers went either to the front or to laboratories formed for developing and testing methods likely to be of use to the fighting services. Our own workshop was employed in making gauges, and all the research at the laboratory was war-work. Soon after the end of the War my duties as master of Trinity obliged me to resign the professorship. The University was fortunate enough to induce Sir Ernest Rutherford to take the post. At the same time, with great kindness and consideration, they gave me a position which enabled me to retain my connexion with the laboratory which for more than forty years had given me unrivalled opportunities for doing the work I liked best, which has brought me many cherished friends and has created rich memories of kind acts, good fellowship, and goodwill.

James Clerk Maxwell.

By Sir Joseph Larmor, F.R.S.

THE course of evolution of the career of a man of genius is always an interesting, and should be an instructive, study. In the case of Clerk Maxwell the materials are ample, thanks to the care of his two biographers, one of them a classical scholar with Greek predilections, the other his intimate and sympathetic scientific assistant. Their account leaves an impression of the absence of any formal education outside his home life. His father was his chief early friend; his real intellectual initiation was identical with his amusements, mainly concerned with dynamical contrivances such as spinning tops, and extending into explorations in practical hydrodynamics by feats of swimming in the bath. Perhaps the Scottish atmosphere of practical engineering, fanned into interests of pure science by men such as Robison, Kelvin, Rankine, explained the origin of this mental bent; but it does not account for the literary grace and charm of his writing.

Another main formative influence was the Scottish Calvinist theology, in its more humane and devotional aspect, supported by intimate conversance with the phrasing and poetry of the English Bible, which has so often been the well-spring of distinction in literary expression. This Puritan trend, while it treasured the historical formularies of the Scottish Church, was in him far from sectional; it ramified into enjoyment of literature, such as the poetry of Milton, and also the descriptive and evolutional poetry of Tennyson, whose influence was still dominant in the Cambridge of his undergraduate time.

Another phase of Maxwell's thought was made public in the biography, in some occasional papers of metaphysical and religious import, which had been read to a private Cambridge society. At the time of publication, as one remembers, the interest of them was regarded as mainly personal, being outside the analytic severity of the British psychology of that period. But they were discovered by Prof. Hoffding of Copenhagen, and have come back to us, in the English translation of his works, as among the competent pronouncements on the philosophy of Nature.

It is Maxwell's main achievement that he unified physical science, by connecting light and radiation with electricity so as to form one interlocked systematic whole. This advance made the Cavendish Laboratory, from its foundation in 1872, the focus of electrical pure science which it has remained ever since. It must have been remarked by students of his writings how abruptly he left off the development of this electrodynamic and optical theme in the last six years of his life, after the publication of the treatise on "Electricity and Magnetism" early in 1873. For example, no question ever occurred as to the dynamical riddle, then prominent in physical speculation, which was presented by the Fresnel laws of refraction of optical waves: though when Helmholtz, and Lorentz, and J. J. Thomson entered into the study of his theory, they at once recognised independently that the form, at any rate, of these laws was immediately involved, while FitzGerald, going deeper, had already connected the electric theory intimately with the entire *corpus* of the optical theories of MacCullagh.

FIG. 3.—JAMES CLERK MAXWELL, Director 1871–79.

One reason may have been Maxwell's preoccupation with fundamental objections of fact, operating against his views. His dynamical mentor, Lord Kelvin, to whom he largely owed the impulse to the elucidation through kinematic models of deep-seated physical phenomena, had here failed him, and to the end of his days held to the view that the foundations of the electric theory of light were unintelligible, by which he seems to have meant not sufficiently disentangled dynamically, his own fundamental developments on latent momenta notwithstanding. The wide discrepancy between the index of refraction of a substance and the square root of its dielectric inductive constant was such a threshold difficulty of fact, and loomed important in those days when the influence of dispersion was not very fully recognised. The first fundamental service of the illustrious Boltzmann to the theory of his master in research was the measurement of the dielectric constants of gases, resulting in confirmation of Maxwell's law for such simple forms of matter: while the experimental work of Hopkinson on organic compound substances also brought out significant correlations.

Curiously enough, it is now recognised universally, on the initiative of the late Lord Rayleigh, that Maxwell himself had been the pioneer in clear-cut dynamical atomic views of dispersion. He had formulated a fully illustrative scheme, in the guise of a rather detailed examination question in the Cambridge Mathematical Tripos of 1869. This must have implied that the floating dynamical instincts of that time were adequate, at any rate in the view of himself and his co-examiners, for a rapid apprehension and verification of the ideas involved; while the collections of Maxwell's tripos problems, that were treasured and utilised in Cambridge teaching, must have made them not unfamiliar to expert optical students.

There is a cognate question, why in his expositions Maxwell made so slight use of moving electric charges as the originators of the electrodynamic fields which, after the example of Faraday, were his main concern. For the atomic constitution of electricity had been fully established by Faraday's own laws of electrolysis, as Helmholtz afterwards emphasised. The idea of electrons acting on one another through a law of attraction at a distance had been long before placed by W. Weber at the foundation of the reasoned exposition of his fundamental electric measurements. Maxwell himself hovers around the phrase 'atoms of electricity.' He even sets in special prominence the remark of Gauss that what was needed was, above all, some notion of how influence was propagated in time between the sources of the electric manifestations. Gauss confesses that he had not been able to find it; while Maxwell implies that it now lies exposed in his equations of the electrodynamic field. Yet he did not pursue this path. Hertz found no difficulty, in 1887, in determining, on Maxwell's principles, the radiation from a vibrating source such as an oscillating electron. Indeed FitzGerald had already, five years earlier, incidentally determined the nature and amount of the radiation from a rapidly alternating current circuit, that is, from a magnetic vibrator; and on the same occasion he pointed out that a spark from an electric accumulator, discharged through a small resistance, ought to produce electric waves as short as ten metres or less. He thus was well qualified to expound Hertz's epoch-making detection of the Maxwellian waves in free space, in an address to the British Association soon after it was announced.

In other respects also Maxwell had largely confined himself to the medium of electric propagation as a whole, as modified by its content of material atoms and ions in bulk. He had measured, incidentally, with the assistance of Hockin ("Treatise" § 798; more fully in the Memoir[1] of 1864), the transparency of metallic foils such as gold-leaf, and found that it implied effective electric conductance far smaller than the steady value as determined on a bridge. The natural reason for this discrepancy he indicated: also the reason why electrolytes are not opaque; but there he left it, for indeed the relevant experimental knowledge was as yet a blank, while other subjects were pressing on him. We may perhaps add to this the distractions involved in the creation of the Cavendish Laboratory, and the laborious editing and expansion of the Cavendish electrical manuscripts.

In the same context ("Treatise," § 792; more fully in the Memoir of 1864, § 107) he propounds very briefly his law of radiation pressure, now fundamental in physics and astronomy; he tries to estimate the magnitude of the pressure for sunlight, coming to grief in detail over the arithmetic. He perhaps reached the law more by physical instinct than by demonstration. If we imagine a limited train of electric waves reflected back at a perfect conductor, a current sheet is induced on it, and the Amperean force on that sheet constitutes a pressure of the train on the conductor. But the train was originally isolated in space, and will again be isolated with only its direction reversed; thus there is no other source for the pressure exerted by it, on the electrons of the current, but a change, here a reversal, of momentum associated somehow with the radiation. This is the idea developed directly in experiment by Poynting, that a train of radiation is a carrier of momentum. Maxwell associated the pressure with his quadratic stress, in origin purely formal, in the electrodynamic field. Close scrutiny, first in time by Lorentz, reveals, however, an outstanding motional part of the mechanical force which is not absorbed into that stress-tensor, significant though it was; and Poincaré and Abraham remarked that it was just such as could arise from a distribution of momentum in the field, thus without vitiating the stress-representation. The complete forcive on the material content of any region is then expressed as the resultant of this formal electromagnetic stress over its boundary, when there is such stress there, together with the rate of communication of this aethereal momentum throughout its volume: if there is no material content these will balance.

It is, then, the transfer of this postulated momentum of radiation that constitutes radiation pressure on material bodies. The transfer is effected, as above, through Amperean force on the current of electrons. Reversing the argument, radiation pressure, as experimentally confirmed by Lebedew, Nichols and Hull, Poynting, implies momentum in radiation; and its existence to the requisite amount implies a reality, of some kind scarcely yet fully explored, in the Maxwellian quadratic field-stress. An intimate knowledge of the structure of the electron which sustains the stress ought to involve both its own dynamical nature and the structure of the field in which it subsists.

It is not necessary to follow up Maxwell's share in the practical settlement of the scheme of electric units, the essential preliminary to the present electrotechnic age; in that Kelvin was the leader. But we may note his early memoir in determination of the nature of subjective colour, in which he verified with precision the surmise of Young, following on Newton, while Maxwell himself was followed by Helmholtz and by Rayleigh, that all the gorgeous play of colour that is a main glory of our natural world arises from combinations of only three independent elements.

It has been already remarked that Maxwell added little in later life to the essentials of the electric theory. The first edition of the "Treatise" had obviously been thrown hurriedly into the press, in a series of rather disjointed fragments which taxed the ingenuity of dynamical interpretation of his British disciples for years; some additions for the early chapters of a second edition were mainly developments of the usual standard knowledge. But he could still be drawn on the subject. Compare his answer in keen and humorous verse to Tait ("Life," p. 684 (1877), already however in "Treatise" (1873), § 577), who proposed apparently to repeat with a spinning excited dielectric disc Rowland's then recent experiment of the magnetic convection effect of a charged rotating disc, as was afterwards carried through by Rontgen. He wanted Tait to spin instead a copper coil with galvanometer in circuit, suddenly to arrest its motion, and note if there was any result; for that would give "the electric current's true direction," or alternatively let it "be your boast to prove . . . that there is no Electric Fluid." This test for sensible inertia of the electrons, as we would now say, has been carried through to success in America only the other day.

---

[1] The abstract of this memoir (*Roy. Soc. Proc* 13, pp 531-536), accidentally omitted in the "Scientific Papers," is an interesting general exposition of the author's ideas, largely in line with modern points of view

Plenty of electric discussion was, however, going on, especially in the years just after Maxwell's death. It was regarded as a great improvement when Heaviside and Hertz, nearly simultaneously, got rid of his vector potentials as being mere mathematical figments, though with him of heuristic dynamical origin; yet the two resulting circuital relations, as Kelvin called them, had already been formulated long before by Maxwell himself, as a concession to a demand for the essential outcome of his theory, in concise form freed from tentative dynamical implications. But these circuital equations are concerned only with the smoothed-out electrodynamic fields. Ultimate dynamical theory, going back to the sources of the field, has not yet been able to do without their vector potentials. Nowadays the circle has indeed gone round full tilt; we have been familiarised with the point of view that the electric and magnetic fields, so tangible in the world of engineering, are in theory only two partial aspects of one six-vector, itself the (Hamiltonian) gradient of a fourfold vector potential that alone is fundamental in Nature, as presented to our minds.

Maxwell's other main contribution to science, equally monumental, lay in the domain of the molecular kinetic theory of gases; it provided the more severe mathematical occupation of his later years. He had taken over the subject in his early days from Joule and Clausius and their predecessors, in the form of a rough *aperçu* of the phenomena of a crowd of independent moving molecules: he converted it into an exact theory, thereby creating the science of statistical dynamics which dominates modern molecular physics. The root principle of that science is Maxwell's law of distribution of velocity, or of other quality, in a multitude of molecules which has attained a steady state. As results there came to him exact dynamical theories of friction and diffusion and conduction of heat in gases, and analytical developments for rarefied gas arising out of the phenomena revealed by the Crookes radiometer. Here also Boltzmann was in readiness to follow up this train of research. From their memoirs in general statistical dynamics, the law of equipartition of energy among the various modes of molecular freedom stood out as a cardinal result. The problem of how the inadmissible consequences of this law are to be evaded has opened up new regions of physics, practical as well as speculative, which at present tend to dominate the whole field.

A characteristic illustration of his genius was the early enforcement of the averaging character of the processes of thermodynamics, by appeal to the possible achievement of ideal minute intelligences, named Maxwell's demons by Kelvin, who could by merely guiding or sifting interference upset the fundamental principles of that science; this arresting quip carried the new doctrine of the statistical character of natural law for molecular structures into regions of thought where abstract dynamical argument could scarcely have penetrated. His lucid expositions in formal thermodynamics need only be mentioned; in them he appeared mainly as the simplifier of the fundamental advances achieved in the American work of Willard Gibbs, the foundation of modern physical chemistry.

Maxwell spent his summers on his small estate of Glenlair in Galloway, among his own people, living as a Scottish laird. Doubtless it was there, among the solitudes of the hills, that illumination mainly came. In the autumn he usually attended the British Association, where, as one used to hear, his gaiety and humour were looked forward to as enhancing the value of the annual scientific discussions, then at their prime. The writer recalls that, returning to Cambridge as an undergraduate one October, a man of the type of a country farmer came into his compartment of the train at Dalbeattie, remained silent for a time, then remarked with emphasis, as something that concerned the world to know, to this effect: Clerk Maxwell has been taken away, mortally stricken; he will never come home again. He died in 1879 at only forty-eight years of age.

Lord Rayleigh.

By Sir Arthur Schuster, F.R.S

MAXWELL'S health began to fail in the early part of 1879. Troubled by his wife's illness, which weighed heavily upon him, his accustomed good spirits had left him; but there were no signs that he himself was suffering from a mortal disease until his return from the summer holidays, when we were shocked to hear that he had only a few weeks to live. His death was a calamity which might have been fatal to the continued prosperity of the Cavendish Laboratory had Lord Rayleigh not consented to accept the professorship. His hesitation and the pressure put upon him by those who had the interest of the laboratory at heart, are set out in the 'Life' of the father written by the son.

After his election, Rayleigh lost no time in making plans for the conduct of his new duties. I am sorry not to have preserved a letter I received from him asking whether I had any suggestions to make, as I had gained some experience in its working during the two years I had spent in the laboratory. Others received similar requests, but I doubt whether the new director of the laboratory received any useful hints on essential matters.

On his own initiative Rayleigh adopted a definite and novel policy, its essential point being the fostering of a spirit of community among the advanced students. To make a beginning, he desired to identify the laboratory as a whole with some research in which a combination of workers was necessary. The question of electrical units had, at that time, gained practical importance and the subject seemed suitable for a combined attack. There was the additional reason that Maxwell had been connected with the original determination of the Ohm fathered by the British Association, and that the principal piece of apparatus, the rotating coil, was preserved in the laboratory.

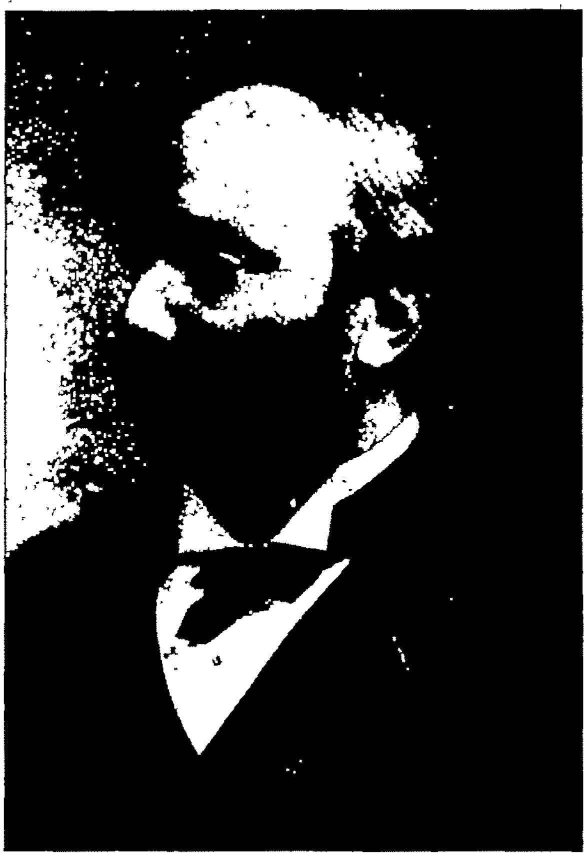

Fig 4.—Lord Rayleigh, Director 1879–84.

Different methods of procedure having led to values which differed more than was desirable, Rayleigh decided to repeat the former work, using the same coil, but paying more attention to what others might have considered minor details. The method by which the rotational velocity of the coil was kept constant was simple and effective, and the same applies to the very ingenious method devised to compare the frequency of the tuning-fork, to which the rotation was referred, with the rate of a standard pendulum clock. When sufficient experience had been gained with the original coil, a new one was constructed giving a result which was decidedly more accurate than any obtained up to that date. Rayleigh was disappointed in his original desire, no volunteers besides myself offering to help, until Mrs. Sidgwick joined us, and the later history of the research is well known.

I may, perhaps, here refer to a personal recollection which has always remained in my mind. During the early stages of the investigation of the Ohm, Lord Rayleigh made the remark to me that this was the first piece of work he had undertaken that required great accuracy of measurement, and he added that he was not at all sure that he would really like it. I replied that I felt sure that the satisfaction of getting another decimal place in a physical constant was a pleasure which would grow on him more and more. Later events, I think, justified my remark.

Persevering in his desire to form a kind of research community within the laboratory, Rayleigh introduced an innovation that may seem trivial, but has been effective in more than one laboratory since. A tea-interval was introduced, during which the different workers could meet and join in informal discussion on scientific problems. Tea was served in a room in which other experiments were kept going, and those who had the privilege of attending these informal scientific meetings will more especially remember the water jets breaking into drops, and the effects of electricity on the appearance presented by them. There were also the spinning colour discs in which we could compare our colour senses.

A good example of Rayleigh's method of work was shown by the little appliance made with card-board, sealing-wax, simple glass lenses, and a prism or two, by which he could determine the relative amount of red and green required by different persons to produce the yellow of a sodium flame. By comparing the results of different observers it was found that, while most persons agreed fairly well in their estimate, there are anomalies which run in families. Lord Balfour and two of his brothers, for example, required a considerably larger proportion of green to get the yellow sensation. With a more elaborate apparatus designed by Rayleigh, I examined, on my return to Manchester, seventy-two persons and found among them four possessing the same peculiarity and one with an anomaly in the opposite direction. Among the four was a woman with two of her three sons. It is a curious coincidence that the colour sense of Clerk Maxwell was, and that of J. J. Thomson is, affected in the same way. An examination of the present director's sight is obviously indicated.

Though not belonging to the Cambridge period, Rayleigh's great work on the weighing of gases should be mentioned, because it was really planned at Cambridge. He frequently referred to the desirability of keeping a research going as a 'stand by,' that is, an investigation which presumably could be continued for a long time and dropped or taken up again as more urgent demands had to be satisfied or a slack time occurred. His choice fell on the weighing of gases, because he was always impressed by the probability of a unity of matter and the likelihood of the correctness in some form or other of Prout's law. Quotations from his address as president of Section A of the British Association giving his views on the subject will be found in the biography written by his son.

During Rayleigh's tenure of office at Cambridge a systematic and very successful instruction in laboratory work was introduced by Glazebrook and Shaw. For this and research purposes a substantial annual income was required, and Rayleigh raised a fund of 1500*l.*, to which he himself contributed one-third.

When he gave up the directorship of the Cavendish Laboratory, it was in a highly efficient state both as a teaching and research institution.

Sir J. J. Thomson, O.M., F.R.S.

By Sir Oliver Lodge, F.R.S.

HOW much less the world would know if the Cavendish Laboratory had never existed; and how diminished would be the glory even of that laboratory if Sir J. J. Thomson had not been one of its directors! We used to think of him as one of the younger physicists; but now that his seventieth birthday is being celebrated that notion must be given up, even by his seniors. But, whether young or old, we have all venerated him for his brilliant achievements.

The discovery of the electron and the foundation of the electrical theory of matter cannot, any more than other fundamental discoveries, be attributed to any single man: these great advances are the outcome of the work of at least a generation. To them Helmholtz, Crookes, Johnstone Stoney, Sir Joseph Larmor, and in the electrolytic stage even Faraday, have all contributed; and, doubtless, in mentioning some names I am omitting others. But researches into the phenomena connected with the discharge of electricity through gases have been Sir J. J. Thomson's special field; and, as Clerk Maxwell hinted would happen, that branch of inquiry has thrown great light upon the nature of electricity itself. Very few before our time can have supposed that electricity was discontinuous. Maxwell's equations and Cavendish's experiments either postulate or appear to demonstrate continuity and incompressibility. That electricity was a fluid, comparable in any respect to a gas, seemed like a popular superstition. The discovery of a discontinuity in Nature must always have notable consequences; and though we may be willing to grant that ultimately every atomic character will be resolved into a deeper-seated and more fundamental continuity, yet for a long time it will be the business of science to absorb and work out the consequences of every discontinuity that is revealed.

John Dalton was the earliest to emphasise the chemical discontinuity of matter. J. J. Thomson is likewise the first to emphasise effectually the atomic character of electricity. His work is a happy combination of experimental and mathematical ability. He arranges ingenious experiments to display and dissect the phenomena; and at the same time most skilfully applies dynamics to analyse those phenomena in an illuminating and metrical manner. In his hands the magnetic deflexion of cathode rays observed by Crookes, coupled with certain other experiments by C. T. R. Wilson and J. S. Townsend, sufficed to determine the mass and the speed of the electric particles; and when electric deflexion of cathode rays was combined with magnetic deflexion, the determination could be made in a particularly neat and convincing manner. So that when Sir J. J. Thomson gave an account of his researches throughout the years 1897 and 1898, before Section A of the British Association meeting at Dover in 1899 (in the presence of a number of Continental physicists, many of whom had come over that day from Boulogne), the whole world rose to the conviction that a new era had dawned in electrical science. A foundation-stone was then laid for the innumerable researches which have gone on during the present century in every laboratory and library of the world.

The facts are so well known now that it is needless to elaborate them: within thirty years they have become almost ancient history. Naturally the renowned discoveries of Becquerel, Röntgen, and Madame Curie fell into line. The discovery of Zeeman, verifying that the radiating particle was not an atom but an electron, worked out initially by the genius of H. A. Lorentz, fell in also with a classical theory of radiation conforming to ideas promulgated by Hertz and Larmor and FitzGerald; though it is true that certain difficulties and puzzles afterwards arose, in which all physicists, including J. J. Thomson himself, are now deeply involved.

FIG. 5.—SIR J. J. THOMSON, O M., F.R S., Director 1884–1919

We used to think that Clerk Maxwell had explained to us the nature of light; and so no doubt to a great extent he had; but our theory of the emission and absorption of light has been singularly complicated by the action and reaction between electrons and radiation, to which O. W. Richardson, Barkla, and other experimenters, including Compton, have contributed so much information. Especially have both complication and illumination been enhanced by the discovery of that new discontinuity which now penetrates our treatment of every interaction between ether and matter—the outcome of singularly successful speculative reasoning by Max Planck at the beginning of the present century.

The accuracy with which both the charge and the mass of the electron are now known (largely through the ingenious measurements of Prof. Millikan), and the researches of spectroscopists all over the world, from Kayser and Runge, Schuster and Hicks, Balmer and Rydberg, down to Prof. A. Fowler—illuminated as they are by the discoveries of Rutherford and the brilliant constructions of Bohr—have raised an enduring monument, a sort of cathedral, glorifying the electrical theory of matter. To the completion of that splendid structure, the present generation, and probably many future generations, are contributing and will contribute. All this must be a great satisfaction to the Master of Trinity, who is still so happily engaged in his own researches that he has perhaps scarcely time to bethink himself of the beauty of the edifice which has been raised on his foundation-stone.

Of course J. J. Thomson has done many other things. At a very early stage he secured the Adams Prize for a theory of the behaviour of vortex rings, which may still one day be usefully drawn upon when the hydrodynamical structure of the ether, already begun long ago by Larmor, is seriously undertaken. Again, the electrical theory of matter would be nowhere if we did not know that an electric charge possessed inertia. The resolution of matter into energy, insisted on by the theory of relativity, has as one of its props that early paper of J. J. Thomson's in 1881 (forty-five years ago!), in which he calculated the extra mass conferred on a body by an electric charge; a suggestive idea to which both he and Heaviside contributed the further illuminating fact that that inertia would be increased by locomotion; a prediction which, when verified by Kaufmann, made an electrical or ether-field theory of matter inevitable.

Thomson did not limit himself to metrical determinations about negative corpuscles and cathode rays. He attacked also the positive or matter rays; and thereby developed a fundamental technique of positive-ray analysis, which speedily detected a variant of neon, and then in the hands of Aston defined atomic weights with altogether unexpected precision. This method, brilliantly and pertinaciously applied, has fully upheld the isotopic conception of Soddy (preceded as that was by the unorthodox speculation of Crookes at the Birmingham meeting of the British Association in 1896), and has thereby not only brought to our ken a host of new substances with similar chemical but different physical properties, but also has established in modified form the hypothesis of Prout, that atomic weights are really whole numbers, of which hydrogen is very nearly, though not quite, the common unit.

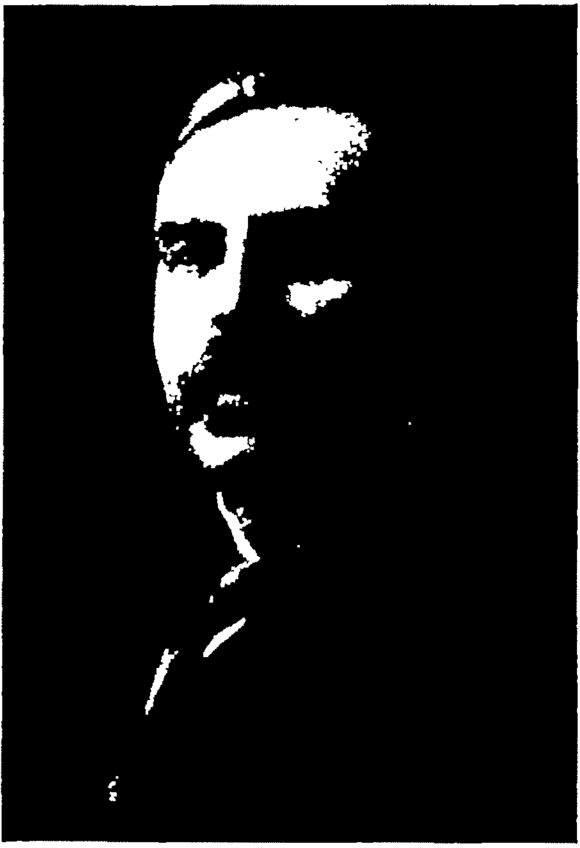
Readers who wish for a more detailed reminder of the steps which have led to these great advances may refer back to NATURE, vol. 91, p. 1, where Prof. Righi of Bologna contributes an article appreciating, from the Continental point of view, the work of Sir J. J. Thomson up to the date 1913.

Students and disciples all over the world could contribute far more details. His own son, the professor of physics at Aberdeen, is one of the brilliant products of the Cavendish Laboratory; and many prominent physicists, such as the present Lord Rayleigh, could testify with intimate knowledge of the work of that laboratory during Thomson's régime. They know the doubts and hesitations which had to be set at rest before the absolute uniformity of electronic charges could be confidently asserted. They know the persistent help given by Mr. Everett, his laboratory assistant for nearly forty years. They are acquainted with the incipient stages of many discoveries. But an older physicist esteems it a privilege to write this brief appreciation of the achievements of one who has worked with unexampled power in the borderland between chemistry and physics, who has introduced into that great science of chemistry revolutionary conceptions the end of which none of us can see, and who is still happily flourishing and active.

Sir Ernest Rutherford, O.M., P.R.S.

By Prof. NIELS BOHR, For.Mem.R.S., University, Copenhagen.

FOLLOWING the kind invitation of the editor to write a few words in appreciation of the work and influence of the present director of the Cavendish Laboratory, I presume that the readers of NATURE will not need any detailed exposition of his achievements. As, however, I am one of those who have had the good fortune to come into close personal and scientific contact with Sir Ernest Rutherford, it is a great pleasure to me to try to describe briefly how we, who are proud to count ourselves among his pupils, regard him.



Photo] [J. Russell and Sons.

FIG. 6.—SIR ERNEST RUTHERFORD, O.M., P.R.S., Director 1919– .

My own acquaintance dates from the period when Rutherford, after years of ardent and successful collaboration with Sir J. J. Thomson in the Cavendish Laboratory, had left Cambridge, and—after his stay at McGill, where his work on radioactive substances had established his fame—in Manchester had founded a school for investigations in radioactivity. This centre attracted young scientists from all parts of the world. In the spring of 1912, on my first visit to Manchester, the whole laboratory was stirred by one of the great discoveries which in so full a measure have been the fruits of Rutherford's endeavours. Rutherford himself and his pupils were eagerly occupied with tracing out the consequences of his new view of the nuclear structure of the atom. It would give only a poor impression of our trust in his judgment for me to say that nobody in his laboratory felt the slightest doubt about the correctness and fundamental importance of this view, although naturally it was much contested at that time. I remember being told by Hevesy soon after my arrival the story circulating in the laboratory of how Rutherford, shortly before his discovery, in a conversation with Moseley expressed the opinion that after all the troublesome investigations of the preceding years—during which he had such faithful assistance from Geiger—one would have had quite a good notion of the behaviour of an α-ray, were it not for the return of a minute number of these rays from a material surface exposed to an α-ray bombardment. This effect, though to all appearances insignificant, was disturbing to Rutherford, as he felt it difficult to reconcile it with the general ideas of atomic structure then favoured by physicists. Indeed, it was not the first, nor has it been the last time, that Rutherford's critical judgment and intuitive power have called forth a revolution in science by inducing him to throw himself with his unique energy into the study of a phenomenon, the importance of which would probably escape other investigators on account of the smallness and apparently spurious character of the effect. This confidence in his judgment, and our admiration for his powerful personality, was the basis of the inspiration felt by all in his laboratory, and made us all try our best to deserve the kind and untiring interest he took in the work of every one. However modest the result might be, an approving word from him was the greatest encouragement for which any of us could wish.

When the War broke out, the little community in his laboratory was dispersed. Having, however, then taken up a lecturing post in Manchester, I had the opportunity in the succeeding years of witnessing the undaunted spirit and never-failing cheerfulness of Rutherford even in the most difficult times. Although the study of the more practical physical problems arising in connexion with the defence of his country took up practically all his time and energy in those years, he could still towards the end of the War find leisure to prepare for, and finally accomplish, perhaps his greatest scientific achievement, the transmutation of an element through the disintegration of the atomic nucleus by impact with α-rays; an achievement which may be said indeed to open up a new epoch in physical and chemical science.

Just at this time Rutherford was, on Thomson's retirement, offered the directorship of the Cavendish Laboratory as his unrivalled successor. I remember on a visit to Manchester during the Armistice hearing Rutherford speak with great pleasure and emotion about the prospect of his going to Cambridge, but expressing at the same time a fear that the many duties connected with this central position in the world of British physics would not leave him those opportunities for scientific research which he had understood so well how to utilise in Manchester. As everybody knows, the sequel has shown that this fear was unfounded. The powers of Rutherford have never manifested themselves more strikingly than in his leadership of the Cavendish Laboratory, the glorious traditions of which he has upheld in every way. Surrounded by a crowd of enthusiastic young men working under his guidance and inspiration, and followed by great expectations of scientists all over the world, he is in the middle of a vigorous campaign to deprive the atoms of their secrets by all the means which stand at the disposal of modern science.

The Cavendish Laboratory: 1876–1900.

By Sir Richard Glazebrook, K.C.B., F.R.S.

It is fifty years since I first entered the Cavendish Laboratory. Eight years previously physics, in the form of questions on heat, electricity, and magnetism, had become a part of the Mathematical Tripos, and in 1869 a syndicate had reported in favour of founding a special professorship to take charge of these subjects, providing him with a laboratory, a demonstrator, and apparatus to make his teaching practical. Two years later, in 1870, the Duke of Devonshire offered to provide the material part of the scheme "so soon as the University shall have in other respects completed its arrangements for teaching Experimental Physics."

Clerk Maxwell became professor on March 8, 1871, and the laboratory was handed over to the University by its donor, the Chancellor, on June 16, 1874, confident, as he said, "that within its walls researches will be carried out which will advance to no small extent the fame of our ancient University." A prophetic statement; for within those walls have worked Maxwell, Rayleigh, Thomson, and Rutherford, men whose names will ever be landmarks in the history of British physics.

To complete the history of the building, a large ground-floor room for the practical instruction of the M.B. students was added in 1893, while in 1906 Lord Rayleigh offered to devote the greater part of the Nobel prize awarded to him to defraying much of the cost of a new wing; this was completed in 1908. In more recent years the erection of the new engineering laboratory has set free buildings and space adjoining the Cavendish, and a further important extension has been added to the laboratory.

To go back, however, some fifty years. In those days students came slowly. W. M. Hicks was the first. Wm. Garnett had become demonstrator on the opening of the laboratory. J. E. H. Gordon was the first to submit for publication the results of a research conducted at the Cavendish in a paper on the magnetic rotation of water, read before the Royal Society in 1875. When I became a student along with W. N. Shaw and Poynting in 1876, Chrystal and Saunder were at work on the verification of Ohm's law; Schuster joined a few months later. W. D. Niven had an investigation in progress, and soon afterwards Donald MacAlister carried out a modification of the well-known Cavendish experiment on the inverse square law of electrical attractions. Poynting began his classical research on the determination of the constant of gravitation during this same period.

Experimental physics was a novel subject at Cambridge. In the Mathematical Tripos of 1876, Lord Rayleigh was an examiner and had set a question on the Wheatstone bridge method of measuring resistance, with an easy rider. I had read carefully much of Maxwell's "Treatise on Electricity and Magnetism," published in 1873, but, alas, had paid no attention to Chapter xi. on "The Measurement of Electrical Resistance." My coach had originally marked it with a large O—omit. It is true he had corrected this later, but I had no idea of what was meant by Wheatstone bridge. My annoyance was great when, on my first visit to the Cavendish, Maxwell himself explained it and I realised the simplicity of the question I had passed over.

In those days there were no organised classes in practical physics. Maxwell set us on to gain acquaintance with some instrument, to adjust it to get it to work and make some measurements. Among my earlier experiences I was told off to measure at regular intervals the E.M.F. of a battery of tray Daniell cells used by Chrystal and Saunder. The instrument with which I had to do this was the large pattern of Thomson's absolute attracted disc electrometer, a horrid monster which few students of to-day have ever seen even in a text-book, and fewer still have used.

However, I soon became absorbed in optical work. Stokes, in his well-known report on optical theories, had described a method of determining the form of the wave surface in a crystal and had applied the method to Iceland spar. He encouraged me to attempt the same for a biaxial crystal and lent me the goniometer he had used. Schuster obtained for me from Hilger a suitable piece of aragonite and the work went on for some time in a dark room at the top of the Cavendish; eventuating in a paper published in the *Philosophical Transactions* for 1878, in which it was shown that Fresnel's wave surface was consistent with experimental results to a very high order of accuracy.

During the progress of the work Maxwell was a frequent visitor, interested in its progress, and ready to help. In the case of a serious difficulty he would remark that others had been asking him questions and he must take time. On one occasion I remember him explaining how thick the crust was in which their

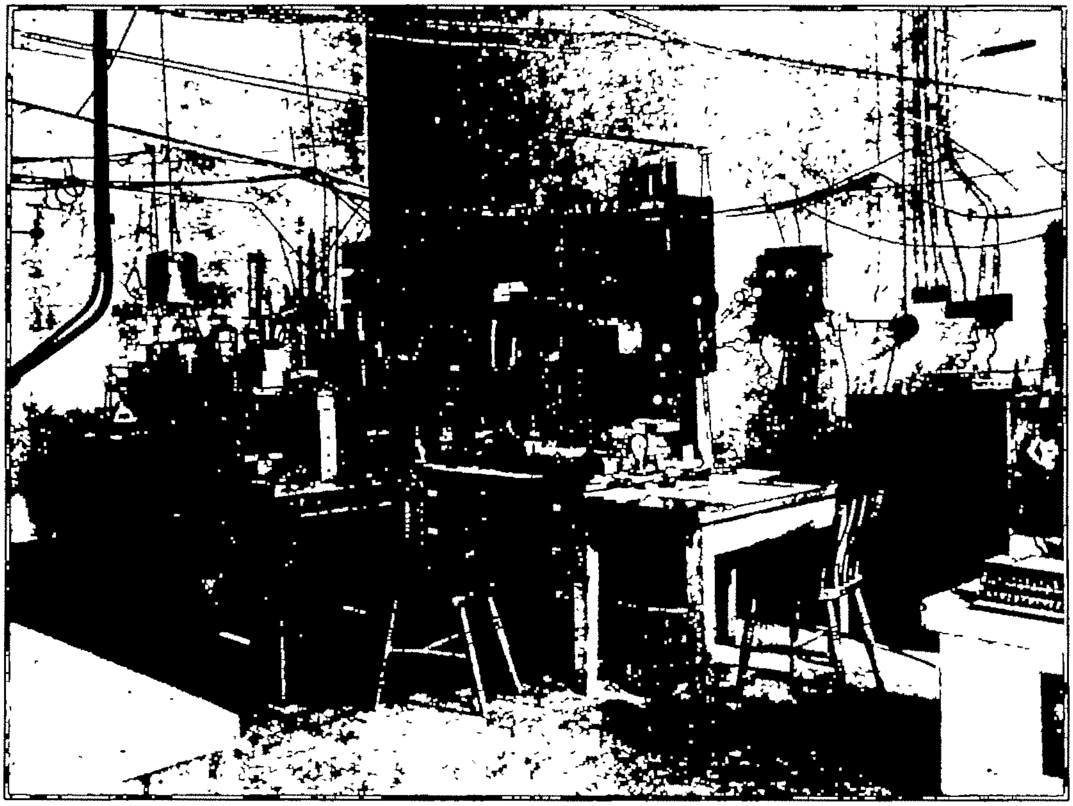


FIG. 7.—General view of Sir Ernest Rutherford's research room. On the extreme left is the electromagnet and microscope used in experiments on the artificial disintegration of some of the elements by bombardment with α-rays. On the extreme right is part of the pillar used by Lord Rayleigh in his determination of the value of the ohm and the ampere. This room was occupied for more than twenty years by Sir J. J. Thomson, for his experimental researches.

questions had encased his brain, but the next day he turned up, accompanied as usual by his dog, with the remark, "If you will alter your arrangements in such and such a way you will find your difficulties disappear," and of course they did.

Those were happy days; there have been many since at the laboratory, but the study of a new subject was full of interest, and the gradual realisation of what experimental investigations with the view of the improvement of material knowledge involved, added much to the pleasure of life and fitted one more and more for the teaching work to come in the future.

In 1879 came a change; Maxwell's health gave way during the Easter term of that year, and after a painful illness he died on November 5. The professorship was continued—it was to terminate originally with the tenure of office of the first professor unless the University determined otherwise—and Lord Rayleigh was appointed on December 12, 1879. He had accepted the post for a limited period—five years—and began work early in 1880. He was anxious from the first to organise regular teaching in practical physics, and appointed Shaw and myself as demonstrators soon after his election. The notice of the work for the Michaelmas term, 1880, after announcing lectures by the professor, by Dr. Schuster on radiation, and by Shaw and myself, continues: "The laboratory will be open daily . . . for those who have had the necessary training. Courses of demonstrations will be given during the Lent term on heat and advanced electricity, and magnetism, and during the Easter term on light, electricity, and sound."

The scheme was something of an innovation in one important detail. Shaw and I were college lecturers, receiving nearly all our remuneration from our colleges; we were among the first to give college lectures in a university building. Hitherto there had been a marked distinction between the lectures of a professor and college teaching; the growth of the natural sciences brought a change. Various colleges still had their own classes and laboratories; at Trinity, Coutts Trotter lectured on physics in college. In physiology and comparative anatomy, however, Foster as Trinity prælector, Frank Balfour and Sedgwick as college lecturers, worked in university buildings. It was clearly out of the question for each college to have its own staff and laboratory in all the new subjects, and so the plan of giving university recognition to college lecturers was gradually evolved, a plan which this year the new statutes have made universal; the formal lectures in all subjects are now given by university officers.

The task we had undertaken was a novel one for us both. Shaw had worked at Freiburg with Warburg and at Berlin under Helmholtz, but at neither place was there organised class teaching in practical physics. My experience had been gained solely as a research student under Maxwell. There were no text-books properly so called. We drew largely on Kohlrausch's "Physical Measurements" and Pickering's "Elements of Physical Manipulation" Pickering at the Massachusetts Institute of Technology had organised a method of instruction which we followed in great measure. There were, it is true, physical laboratories under Wm. Thomson (Lord Kelvin) at Glasgow, Carey Foster at University College, London, Adams at King's College, and Clifton at Oxford. But the time given to practical physics was short, the means of instruction scanty, and there was comparatively little endeavour to teach the principles of physics to a student by means of experiments which he performed himself.

Gradually the system developed; note-books descriptive of each experiment were written, and these in due time became Glazebrook and Shaw's "Practical Physics." The students were taught to describe in their own note-books their work, and enter up their observations; in the advanced class they were expected to read up the theory referred to and work to a high degree of accuracy. The material on which we drew for students was of a very high order. In my class on advanced electricity in 1881, I find the names among others of J. M. Dodds, S. L. Hart, W. B. Allcock, Edward Hopkinson, A. R. Forsyth, R. S. Heath, J. Ryan, and R. Threlfall.

Above all we had the wise counsel and cordial help of the professor: the course was planned and the syllabus arranged after careful counsel taken with him. We could go to him for advice in case of difficulty, otherwise we were free to teach as seemed best and to develop the work in the directions which seemed most desirable. In due time we had efficient helpers, Newall, Wilberforce, Searle, Skinner, Threlfall, Fitzpatrick, Callendar, Whetham, and McConnel, to name only a few, though some of these belong to a later period than that I am now describing.

It was, however, not merely the organisation of teaching which gave interest to the work. The laboratory began to be, to an extent as never before, a centre of new knowledge. A glance at Lord Rayleigh's collected works will show the importance of his output during the five years' tenure of the chair. The experiments of Rowland and Joule had led definitely to the result that the resistance coils constructed by Fleeming Jenkin and Maxwell in 1863 to represent the ohm (10^9 C.G.S. units of resistance) were in error. The Standards Committee of the British Association was reconstituted at Swansea in 1880, and Lord

Rayleigh at once began to take an active part in its work. His first series of experiments with the rotating coil of the original committee, carried out with Schuster, confirmed the fact that there was an error in their determination. Further experiments with a new rotating coil in 1882, and by the method of Lorenz, with the assistance of Mrs. Sidgwick, in 1883, led to definite values from which there has been little variation up to the present. Meanwhile he had arranged that I, as secretary of the B.A. Standards Committee, should undertake to test and issue certificates for resistance coils, and this work went on at the laboratory for the next fifteen years, being ultimately transferred to the National Physical Laboratory.

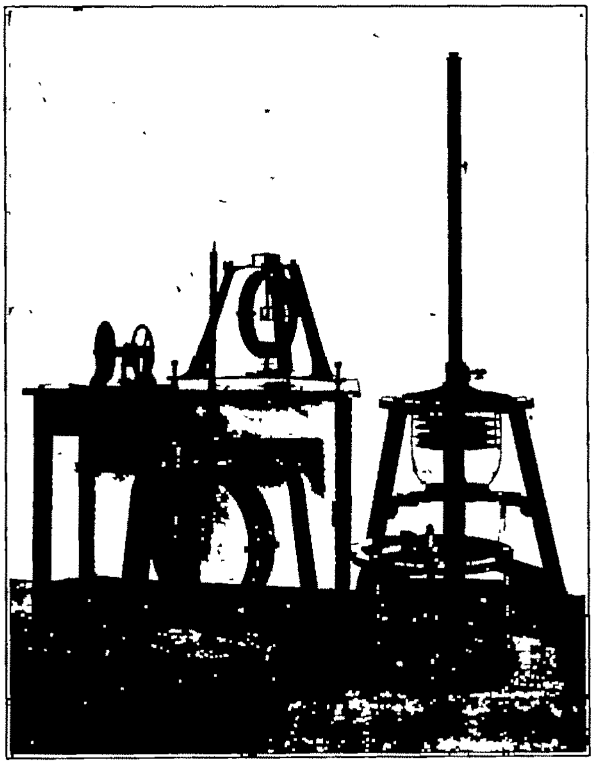

FIG. 8—Some classical apparatus. The coil on the table is the original spinning coil of Maxwell and Fleeming Jenkin used for the determination of the ohm (1864); it is now on loan at the Science Museum, South Kensington. The coil below is the spinning coil of the late Lord Rayleigh, with stroboscopic attachment, used for the determination of the ohm (1882). The coils on the right were made by Chrystal and used by Glazebrook in his determination of the ohm. On the right is Maxwell's apparatus for measuring the viscosity of air at different pressures. A phonic wheel of Rayleigh's stands to the left on the table.

Throughout this period, and indeed until the end of his life, Sir William Thomson was a frequent visitor to the laboratory, enthusiastic always, keenly interested in the experiments in progress, and full of helpful encouragement for us all.

Work on the electrochemical equivalent of silver, and the E.M.F. of a Clark cell, followed quickly. At a later date Lord Rayleigh took an active part in designing the standard ampere balance for the Board of Trade. He acted as president of the International Electrical Conference held in London in 1908 at which the definitions of the International Ohm, Ampere, and Volt were agreed to by delegates representing Great Britain, certain of her colonies, and twenty-two other countries. The results then reached find their main support in his work[1] during the years 1881–1885.

Some of the apparatus used in these and in the earlier experiments of Maxwell is shown in Fig. 8, which is reproduced in "A History of the Cavendish Laboratory, 1871–1910," published by Messrs. Longmans, Green and Co., to which volume I have referred for much in this article. At about the same period the original resistance coils of the B.A. had been brought to the laboratory, and Fleming commenced his long series of electrical researches by a careful intercomparison of these. The Darwins—George and Horace—were at work on the lunar disturbance of gravity. Schuster, in addition to assisting in the electrical experiments, continued his investigations into spectroscopy and radiation. J. J. Thomson's paper—the first dated from the Cavendish Laboratory—"On some Electromagnetic Experiments with open Circuits," appeared in the *Philosophical Magazine* for July 1881. In the previous April his paper on the electric and magnetic effects produced by the motion of electrified bodies had been published; in it he demonstrated that a moving charge will act as though it possessed mass of amount $\frac{2}{3}e^2/a$, where e is the strength of the charge supposed to be treated as a small sphere of radius a. Other papers rapidly followed, while in 1883 a determination of the number of electrostatic units in the electromagnetic unit of electricity was printed in the *Philosophical Transactions of the Royal Society*, and a paper on a theory of the electric discharge in gases in the June number of the *Philosophical Magazine*.

Shortly before his death, Maxwell had called Shaw back from Berlin to undertake work for the Meteorological Council, and thus began, with a paper on the measurement of temperature by water vapour pressure (1883), followed by his report on hygrometric methods (*Phil. Trans.*, 1888), that long series of investigations which has gained him recognition as the leader of modern meteorologists.

My own work on the form of the wave surface of

[1] It may be of interest to compare the values for the ohm (10^9 C G S units of resistance) expressed as the length of a column of mercury found at the Cavendish Laboratory in 1882 and 1883 with the most recent values.

1882	Rayleigh	106·26 cm.
1882	Glazebrook	106·25
1883	Rayleigh and Sidgwick	106·24
1913	F. E. Smith	$106{\cdot}24_5$
1920	Grüneisen and Giebe	$106{\cdot}24_6$

biaxial and uniaxial crystals was continued in 1886 by McConnel in his paper on quartz. I was diverted from optical work by the duties which came to me on my appointment in 1882 as secretary of the Electrical Standards Committee. Chrystal, when at the laboratory, had constructed a ballistic galvanometer and wound a pair of large coils for a determination of the ohm by a modification of Kirchhoff's method. With the aid of two of the senior students, Dodds and Sargant, these were set up and a series of determinations made, with the result already given, practically identical with that obtained by Lord Rayleigh. These same coils were used by him for his Lorenz experiments, and the close concordance of the results is of importance as an error in the calculated value of the mean radius of the coils would affect them in opposite directions.

At the end of 1884 Lord Rayleigh resigned and J. J. Thomson became professor. The work of teaching continued on much the same lines. The new professor realised no less fully than his predecessor the value of practical physics not only as an engine of research but also as an instrument of education.

Thomson, assisted by Threlfall, at once began that series of experiments on the discharge of electricity through gases which has occupied him until now. Newall returned to Cambridge and shortly afterwards became demonstrator in succession to Shaw, who in 1887 was made tutor at Emmanuel College. About this time Newall, Threlfall, Cassie, Wilberforce, Fitzpatrick, Callendar, and Chree were at work on various problems, while Olearski and Natanson were the first of the long series of research students attracted to Cambridge by the growing fame of the professor.

An addition of some importance was made to the laboratory teaching in 1888, when practical classes for medical students were commenced. For some time previously a viva voce with instruments had been part of the first M.B. examination, and the introduction of more definite teaching suited for the examination became desirable; Fitzpatrick took charge of this. Meanwhile the other classes continued to increase, and as the teaching of practical physics spread to the schools it was necessary to devise fresh experiments of a somewhat more advanced character. Searle became demonstrator in 1891 and threw himself with great zeal into this work.

In 1895 a change of far-reaching importance was made in the University regulations. Up to that date research students from other universities had no recognised position in Cambridge; some few there had been, admitted to the laboratories by the courtesy of individual professors. From this time onwards graduates of other universities, and in some cases students who were not graduates, could enter the University for purposes of research if they satisfied the proper authorities of their competence. They could obtain a degree at the end of two years if they submitted to the Board of Studies a thesis which in the opinion of the Board was "of distinction as a record of original research." In the October term after these regulations were passed, Rutherford, Townsend, and McClelland came as the first students; their number is now legion.

Rutherford's earliest work was on a detector of wireless waves. Hertz's experimental verification in 1887 of Maxwell's theory of electromagnetic waves had been received with great interest when first published. We knew the theory to be true—it was Maxwell's—and to have it verified by direct experiment had been no small satisfaction to Maxwell's pupils. I well remember some time in 1896 being taken by Rutherford into his room to see his magnetic detector at work receiving a message from, I think, the observatory.

Meanwhile Thomson had continued his work on the passage of electricity through gases, and the discovery of the Röntgen rays in 1895 gave him and the band of students he had collected a powerful method of investigating the subject. In 1897 came the discovery of the electron. Perrin in 1895, and Thomson two years later, had proved that the cathode rays of Crookes consisted of a stream of particles each carrying a negative charge. Thomson in 1897 measured the ratio of the mass of each particle to its charge and also the velocity with which the particles travel. The quantity, m/e, was found to be much smaller than would be the case if m represented the mass of the hydrogen atom and e its charge. Moreover, its value was independent of the nature of the gas in the tube, and he concluded that we have in the cathode rays a condition "in which all matter that is matter derived from different sources such as hydrogen, oxygen, etc., is of one and the same kind; this matter being the substance from which all the chemical elements are built up."

In the same year, 1897, Kaufmann and Wiechert determined independently the value of the ratio m/e, arriving at similar results. Schuster in 1884 had suggested that if the cathode rays consisted of charged particles it was possible to determine the ratio e/m by a method practically identical with that employed later by Kaufmann, and in 1890 published results of experiments which led to limits for the value of e/m for the cathode rays.

In the following year Thomson showed that the charge e carried by one of his corpuscles or electrons was the same as that of an atom of hydrogen, and from this it followed that the mass of the electron is about 1/1800 of that of an atom of hydrogen. The existence of the electron, the fundamental unit of negative electricity, became an accepted fact, and the long series of modern discoveries connected with the names of Thomson, Rutherford, Bohr, and their pupils was the result.

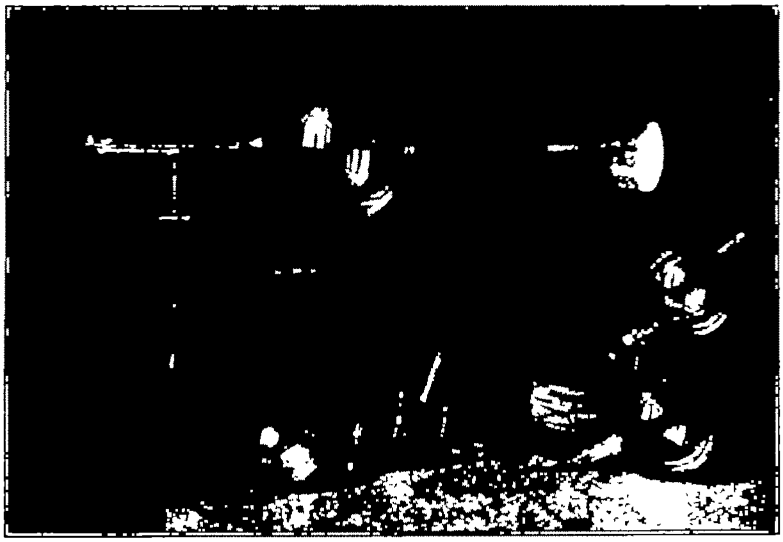

FIG. 9.—Apparatus used by Sir J. J. Thomson in his investigations. The upper tube is an early form of positive ray tube for visual examination of the parabolas. The lower, left hand, tube is one used to show the electrical deflexion of the cathode rays in 1897. By measuring the deflexion of a pencil of rays in an electric as well as in a magnetic field, the velocity and the ratio e/m for the electron were determined. On the right are examples of electrode-less discharge bulbs.

Thomson and his pupils continued this work. McClelland examined the Lenard rays which appear on the opposite side of a thin sheet of metal on which the cathode rays impinge, and showed that they were identical in properties with cathode rays. Stokes had suggested that the X-rays of Röntgen consisted of pulses set up by the sudden stoppage of particles carried in the cathode rays. Thomson investigated the nature of the effects produced by such a sudden stoppage, proving that it would give rise to a thin pulse of very intense electric and magnetic force travelling out from the particle with the velocity of light. He later applied this theory to explain the secondary radiation produced when X-rays fall on matter. Langevin, the first of the foreign students to enter the laboratory under the new regulations, investigated the character of this secondary radiation and published his results in his thesis for the degree of Doctor of Science in Paris.

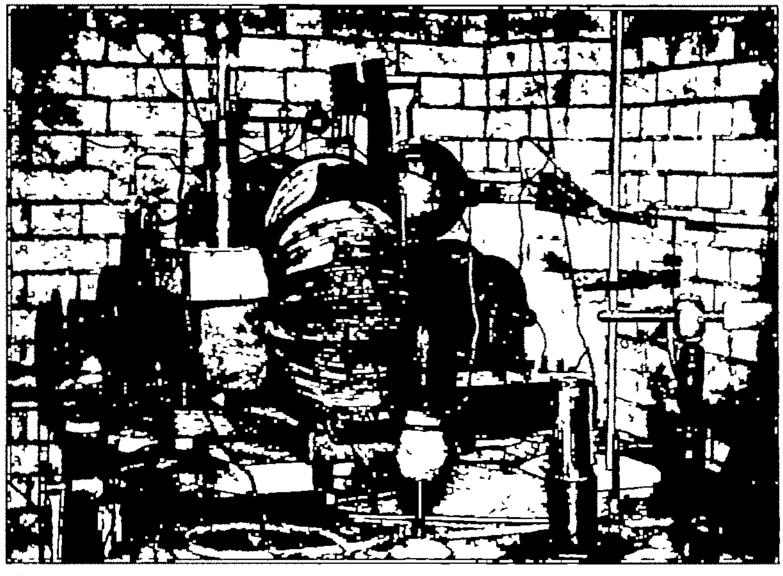

FIG. 10.—Apparatus for the analysis of positive rays by Sir J. J. Thomson's 'parabola' method This was the first made in which the photographic plate could be lowered into position by a vacuum-tight winch. It was in this room, with a slightly modified apparatus, that the duplicate parabolas of neon were first photographed, in 1912.

New knowledge grew rapidly. Rutherford, Townsend, H. A. Wilson, Zeleny, Strutt, and others contributed. C. T. R. Wilson's paper on the condensation nuclei produced in gases by the action of various rays, published in the *Phil. Trans.* for 1899, proved of far-reaching importance. As time went on the influence of the Cavendish researches spread to other universities. Rutherford carried it across the Atlantic to Montreal, Townsend to Oxford, McClelland returned to Dublin, Langevin to Paris, while others came to take their place.

My days at Cambridge closed with my appointment as Principal of University College, Liverpool, toward the end of 1898. Formal connexion with the laboratory had ceased some two years earlier when I had undertaken administrative work for my College. The last experimental investigation I helped to carry out was undertaken along with Lodge, who spent a summer vacation in Cambridge, as an essay to be submitted for a prize offered by Elihu Thomson. The investigation included a determination of v by means of the measurement of the frequency of the oscillations in a circuit of known capacity and inductance, and was published in the Stokes Memorial volume issued in 1899. Up to that time I had been closely connected with the Cavendish for nearly twenty-five years and have written of things I knew. I must conclude now and leave to others more intimately acquainted than myself with the progress of the last quarter of a century to tell in detail what that progress has been. Thomson continued his work until 1918, through the troubled period of the War, when the researches of the Cavendish assisted to the full in the solution of many problems. In that year Dr. Butler, the revered Master of Trinity, died, and Thomson was chosen by the Crown as his successor. He resigned the Cavendish professorship with its charge of the laboratory, and the University created for him a professorship of physics which will cease with his tenure of the post. Rutherford followed as professor, and under his genial direction he and his 'boys' from day to day increase the sum of natural knowledge by their amazing results and add in no small degree to the fame and influence of the Cavendish Laboratory, thus verifying the forecast of its founder more than fifty years ago

---

Research Work in the Cavendish Laboratory in 1900–1918.

By Prof. J. A. Crowther.

The progress of science and the life of a laboratory have little connexion with the artificialities of chronology, and the beginning of the century does not coincide with any natural division in the work of the Cavendish Laboratory. If, for the sake of clearness, we must make a division in what was fundamentally a natural and continuous growth, our most convenient date will be the year 1903, and our obvious landmark the publication of the first edition of Thomson's monumental book, "Conduction of Electricity through Gases." Here we find for the first time a complete and logical account of the solid achievements of the previous eight or ten years of remarkable activity. Here also we find the foreshadowings of the ideas which were to direct and regulate a large part of the work of the succeeding years.

In the main the problems attacked in the years before 1903 were those of the mechanism of the conduction of electricity through gases. Some of these, it is true, were carried over into the succeeding period. Some, perhaps, have not yet been fully solved, but by 1903 the foundations of the subject had been well and truly laid. It had been proved, beyond doubt, that the conductivity imparted to gases by various agents, such as X-rays, the rays of radium, and ultra-violet light was due to the formation of charged particles or gaseous ions in the gas, and many of the properties of these ions had been determined. Rutherford had determined their mobility; Townsend had determined their rate of diffusion through various gases; C. T. R. Wilson had shown that they could serve as nuclei for the condensation of water in a supersaturated space. Thomson had discussed their motion, and shown that in all probability they consisted of single molecules of the gas in which they were formed.

In a closely allied subject Thomson had demonstrated experimentally the existence of the electron, or negative corpuscle as we then called it, and had determined its few simple properties. The measurement of the electronic charge actually falls within the present century, though preliminary experiments had been made somewhat earlier. Determinations were made independently by Thomson and by H. A. Wilson, by somewhat different methods, and were published in 1903. During the same period Zeleny made new measurements of ionic mobilities, which when combined with further measurements on the diffusion of ions by Townsend established conclusively the identity of the charge on a gaseous ion with that on a monovalent ion in solution. These experiments mark the culmination of the first epoch.

When I commenced research work in 1905 the second epoch of activity was already well under way. With the exception of C. T. R. Wilson, who in the advanced laboratory was engaged in imparting to a new generation of students those experimental arts of which he is a master, the first group of workers had all dispersed. Their work, as collected in the pages of "Conduction through Gases," formed our text-book, and was the foundation on which we hoped to build.

It was a very happy, though crowded, community to which I had the honour of being admitted. The space available for research had not been extended since the laboratory was built, and what had been adequate for ten or twelve, the average number of research workers before 1903, was becoming a tight fit now that the numbers had risen to an average of twenty-five. A competent observer records that there was more physics to the square centimetre in the Cavendish than anywhere else in the world, and the resources of the laboratory in the way of apparatus were sometimes severely tested, though I cannot recall that they ever broke down. The oft-repeated legend that we worked entirely with sealing wax and string, though flattering to our technique, has little foundation in fact. The apparatus for the new experiments which we wished to make did not exist. It had to be invented and made on the spot. An adequate workshop, staffed with extraordinarily competent and helpful mechanics, with F. Lincoln as chief, carried us through the worst of our difficulties; while Everett, the professor's private assistant for so many years, was always willing to lend a hand in the worst intricacies of glass-blowing. For the rest there was the spirit of cheery fellowship and good comradeship which extended from the professor to the rawest recruit, and bound us all into a genuine community.

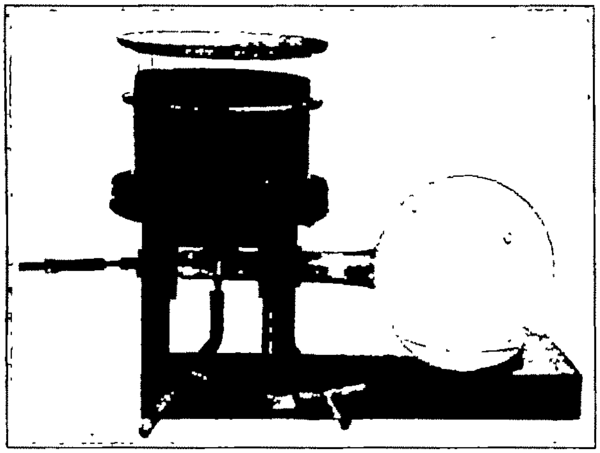

FIG. 11.—Prof. C. T. R. Wilson's original expansion apparatus for making visible the tracks of ionising particles. It was made in the Cavendish Laboratory in 1911 and is the apparatus with which his photographs of the tracks have been obtained.

It is clearly impossible to attempt to give any adequate account of the activities of so many workers, extending for so many years, within the bounds of a single article. A mere list of publications would fill more space than I have at my disposal. I can only outline the general trend of discovery in the laboratory as I saw it, and many excellent pieces of research such as those of Burton on colloids, of Wellisch on ionic mobilities, of Vegard on osmosis, and of C. T. R. Wilson on atmospheric electricity, must pass unnoticed. This is the more unfortunate in that it may tend to accentuate the erroneous impression that the research work of the Cavendish has been entirely specialised and one-sided. This has never been true. Workers with ideas in any branch of physics have always received a warm welcome, and the Cavendish has rarely been without them. The majority of the research workers, however, came to the laboratory as young students, to learn their job, and it was natural and inevitable that their work should be inspired and directed by the genius of Thomson, and should be correlated to the subjects which he had most in mind.

The dominant problem from 1903 onwards was that of the structure of matter, to which the way had been opened by the discovery of the universality of the electron. Thomson's main theoretical contributions to the subject appeared in 1903, 1904, and 1906, and dealt with possible arrangements of electrons to form atomic structures, and the properties—electrical, magnetic, and optical—which might be expected to result from these arrangements. The substance of these papers reappeared, in a somewhat more popular form, in "Electricity and Matter" and the "Corpuscular Theory of Matter." To bring these ideas to the touchstone of experiment was, perhaps, the main preoccupation of the laboratory until the year 1912.

A study of electrical conductors seemed to offer a hopeful line of approach. If the current through a metallic conductor is carried by electrons, which share in the thermal agitation of the molecules, some of them should escape from the surface if the temperature is sufficiently raised. Preliminary experiments on the subject were made by O. W. Richardson so early as 1901, and some of the theoretical consequences were discussed by Thomson in the following year. The subject was hotly pursued by O. W. Richardson in the Cavendish until 1906, and afterwards at Princeton, and has developed into the important branch of physics known as thermionics. Thomson, Horton, and others also made contributions to the subject. The preliminary work necessary to disentangle the genuine effect from the many spurious phenomena which accompany it was tedious and harassing, but important and valuable results were eventually obtained.

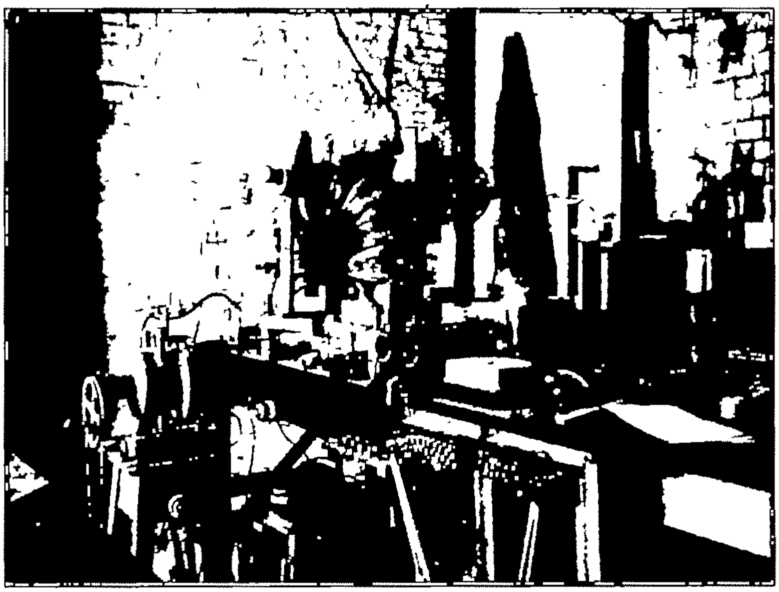

FIG. 12.—The first mass-spectrograph set up by Aston in 1919. This instrument was capable of comparing the masses of atoms and molecules with an accuracy of 1 in 1000. By its means, in five years, more than fifty elements were resolved into isotopes or shown to be simple.

The question of the radioactivity of ordinary materials, which was being investigated in the laboratory about this time by N. R. Campbell and A. Wood, also had its bearings on the main problem. Difficulties were met with in eliminating the effects of penetrating radiations from outside sources and the possibility of small traces of radium in the materials employed, and the results were indeterminate, except in the case of some of the alkali metals, which were found to emit appreciable quantities of β-radiation. Experiments made by Kleeman on the relative ionisation produced by different ionising radiations in gases, by Laby on the total number of ions produced by the complete absorption of the α-rays from uranium in different gases, and by Kaye on the output of X-radiation from targets of various metals, while important in themselves, also had a more or less direct bearing on the main problem of the atom.

In 1906 Thomson returned to the attack and gave the theory of two important methods of estimating the number of electrons in the atom of a given element. One method suggested was to measure the diffusion of a parallel beam of β-particles in their passage through thin sheets of matter. Assuming that the deflexions are due to collisions with the electrons in the atoms through which they pass, a determination of the scattering of the particles should provide an accurate estimate of the number of scattering centres. A second method consisted in measuring the intensity of the scattered X-radiation from a given radiator when subjected to a beam of primary X-radiation. Here again, assuming the correctness of the classical theory of the phenomenon which had already been given by Thomsen, it should be possible to deduce the number of scattering centres from the intensity of the radiation scattered. The experimental working out of both these methods fell to my lot, and kept me occupied from 1906 to 1911. The results showed that the number of electrons per atom was quite small, approximately of the order of the atomic weight, and that the main mass of the atom must be associated, not with its electrons, but with its positive charge.

In the meantime Thomson had himself been investigating the positive charge on the atom by various modifications of the method which had proved so successful with the electron. The results of these experiments on positive rays were published in various papers from 1908 to 1914. The importance of the new method lies in the fact that for the first time atoms could be dealt with as individuals, and not merely in aggregations of many millions. The results of these experiments, together with those of Aston (1919–1925) which led to the discovery of the existence of isotopes and the whole number law for the masses of the atoms, are too fresh in the memory to need further description.

In the meantime new ideas were afloat. The phenomena of secondary corpuscular radiation excited by X-rays, as studied by Innes, and of photo-emission (Hughes and others) were becoming more and more impossible to reconcile with the classical wave theory of light. The theory that the wave front was discontinuous was put forward by Thomson so early as 1907, and experiments to test the matter were made by N. R. Campbell, and by G. I. Taylor in 1909. Laue's discovery in 1912 of the diffraction of X-rays by crystals placed a new weapon in the hands of physicists, and by 1913 W. L. Bragg, working in the Cavendish, had already employed it to measure the distance apart of the atoms in a rock-salt crystal, and to deduce an absolute value for the wave-lengths of various X-radiations. A little earlier (1911–1912), C. T. R. Wilson, by an ingenious modification of his early experiments on the deposition of water vapour on charged ions, had evolved a method of making visible the actual tracks of ionising particles in gases, a method the potency of which has not yet been fully exploited, although it is now in use in many laboratories in all parts of the world. Whiddington, by his experiments on the excitation of characteristic X-radiation by cathode rays (1912), was already approaching the quantum theory of X-ray phenomena. At the commencement of 1914 the stage seemed fully set for a new outburst of activity which should rival even the early days of the laboratory under Thomson.

Alas, however, the world stage was set for quite a different drama, and its research workers found problems for solution far different from those which they had been expecting to attempt. When the laboratory began to fill up again in 1919, it was to learn that its professor had found the double duty of directing at one and the same time a great laboratory and a great college too much for one man's strength and time, and the Cavendish professorship was resigned. This is not the end of the story. Sir J. J. Thomson still continues his theoretical and experimental researches with unabated vigour and success, and under its new chief, Sir Ernest Rutherford, the Cavendish goes on to new problems and new triumphs. But these changes may conveniently mark the end of the present article, which has already exceeded its allotted span, without doing anything like justice to the many old companions and friends by whose side I have worked in the Cavendish laboratory, and whose faces look down upon me from the framed groups upon my study walls. Having worked in the Cavendish they will understand the impossibility of the task I have undertaken, and being Cavendish men they will forgive.

MACMILLAN'S STANDARD BOOKS ON PHYSICS

GENERAL AND REFERENCE

TEXT-BOOK OF PHYSICS. By J. DUNCAN, Wh. Ex., M.I.M.E., and S. G. STARLING, B.Sc., A.R.C.Sc. 18s. Also in parts: Dynamics, 6s.; Heat, Light, and Sound, 7s. 6d.; Magnetism and Electricity, 5s.; Heat, 4s. 6d.; Light and Sound, 4s 6d.; Heat and Light, 6s.

A TEXT-BOOK OF PRACTICAL PHYSICS. By PROF. H S. ALLEN, M.A., D.Sc, and H. MOORE, A.R.C.S., B.Sc. 10s. 6d. Part I. Properties of Matter. 4s. Parts II., III., and IV. Sound, Light, and Heat. 4s. Parts I. and IV. 5s. Part IV. 1s. 9d. Parts V. and VI. Magnetism and Electricity. 4s.

CLASS BOOK OF PHYSICS. By SIR RICHARD GREGORY and H. E. HADLEY, B.Sc. 6s. 6d. Parts I. and II. Fundamental Measurements; Hydrostatics and Mechanics. 2s. 6d. Parts I. II., and III. Fundamental Measurements; Hydrostatics and Mechanics; Heat. 3s. Parts I., II., III., and IV. Fundamental Measurements; Hydrostatics and Magnetism; Heat; Light. 4s. 6d, Part III. Heat. 2s. Parts III. and IV. Heat; Light 2s. 9d. Parts III., IV., and V. Heat; Light; Sound. 3s. Part IV. Light. 2s. Parts IV. and V. Light; Sound. 2s. 6d. Parts VI., VII., and VIII. Magnetism; Static Electricity; Voltaic Electricity. 3s.

EVERYDAY PHYSICS. By H. E. HADLEY, B.Sc. Complete, 6s. 6d. Section I. Fundamental Principles, 2s. 6d.; Sections II.-IV. Sound, Heat, and Light, 2s. 6d.; Section V. Magnetism and Electricity, 2s. 6d.

PRACTICAL PHYSICS: FUNDAMENTAL PRINCIPLES AND APPLICATIONS TO DAILY LIFE. By N. H. BLACK and PROF. H. N. DAVIS. 6s. 6d.

LABORATORY EXPERIMENTS IN PRACTICAL PHYSICS. To accompany Black and Davis' "Practical Physics." 4s. 6d.

INTERMEDIATE COURSE OF PRACTICAL PHYSICS. By SIR A. SCHUSTER, F.R.S., and PROF. C. H. LEES, F.R.S. 6s.

MANUAL OF PRACTICAL PHYSICS. By H. E. HADLEY, B.Sc. 4s.

AN ELEMENTARY COURSE OF PHYSICS. Edited by REV. J. C. P. ALDOUS, M.A. 7s. 6d. Part I. Mechanics; Properties of Matter; Hydrostatics; Heat. By REV. J. C. P. ALDOUS, M.A. 4s. 6d. Part II. Wave Motion; Sound; Light. By W. D. EGGAR, M.A. 2s. 6d.

LESSONS IN PRACTICAL PHYSICS. By PROF. BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Vol. I. General Physical Processes. 7s. Vol. III. Part I. Practical Acoustics. By C. L. BARNES, M.A. 5s.

GENERAL PHYSICS FOR STUDENTS. By E. EDSER, A.R.C.Sc. 8s. 6d.

APPLICATIONS OF DYNAMICS TO PHYSICS AND CHEMISTRY. By SIR J. J. THOMSON, F.R.S. 8s. 6d.

A HISTORY OF PHYSICS IN ITS ELEMENTARY BRANCHES. By PROF. F. CAJORI, Ph.D. 10s. 6d. net.

DICTIONARY OF APPLIED PHYSICS. By Various Writers. Edited by SIR RICHARD GLAZEBROOK, K.C.B., Sc D., F.R.S. Illustrated. In 5 Vols. 8vo. £3 : 3s. net each. The set of 5 Vols., £14 : 14s. net. Vol. I. Mechanics, Engineering, and Heat. Vol. II. Electricity. Vol. III. Metrology, Meteorology, and Measuring Appliances Vol. IV. Optics, Sound, and Radiology. Vol. V. Aeronautics, Metallurgy, and General Index.

On choosing a Loud Speaker

NO one would ever think of choosing a car without a great deal of thought and reflection. Yet how many people will buy a Loud Speaker without previously considering which type is suitable for their particular conditions? Haphazard choice of a Loud Speaker in fact has led to more dissatisfaction with radio than any other cause.

When buying a Loud Speaker consider these points:

1—TONE

First among the essentials of good reproduction is tone. Absolute freedom from distortion and a perfectly life-like rendering of every phase of the broadcast—orchestral and vocal, is necessary. It is upon this that Brown success has been founded.

2—VOLUME

It is essential that a Loud Speaker should be capable of giving a varied volume to meet individual needs; but whether the volume be great or small there must be no trace of distortion. There are very few Loud Speakers capable of rendering with real purity an unlimited amount of volume.

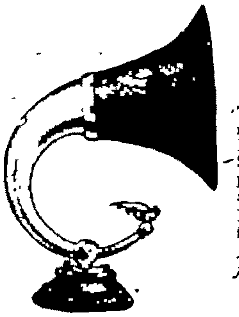
3—NAME

You may be shown Loud Speakers which *look* as good as the Brown, yet at much lower prices. Compare them, though, on quality of reproduction with any Brown—you cannot be other than impressed with the result. The name Brown stands for all that is best in radio reproduction—pure, unsurpassed tone combined with adequate volume.

¶

Illustrated here is the world-famous Brown "Q." It is universally acknowledged to be the height of Loud Speaker perfection.

Price £15 : 15s.



¶

There are nine models in the Brown Loud Speaker range—priced 30s. to £15 : 15s.

Headphones, too, from 20s. to 30s

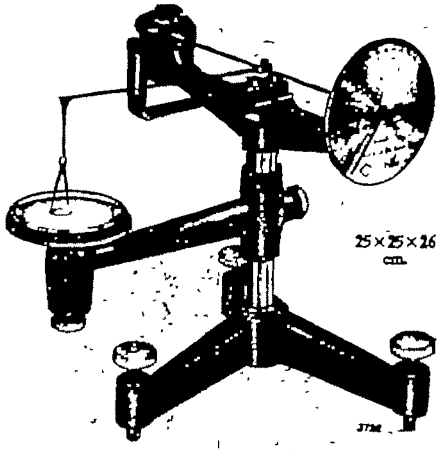
SURFACE TENSION APPARATUS



This apparatus has been designed by Dr. P. L. du Noüy for rapidly and accurately determining the surface tension of liquids. The method is simple, requires only a small quantity (about 1 c.c.) of the substance being tested, and is applicable to practically all kinds of liquids. The instrument is readily standardised with pure water at 20° C.

years in buildings so primitive that one of the Austrian ministers himself described them as "a European scandal."

No wonder, then, that our students went to foreign universities! I believe the first of our scientific men who brought us some of the English research method in natural science was Prof. Boh. Brauner, our distinguished chemist, who studied at Owens College, Manchester (1880–82), and is well known to readers of NATURE.

Thirty years ago I had the opportunity to begin some research at Cambridge at the Cavendish under the guidance of Prof. J. J. Thomson. We were about eleven research students, and made quite a family party, meeting every day at tea-time in the professor's room. Prof. Thomson's discourses on these occasions, on the work going on in the laboratory, and his method of investigation, together with his clear and instructive mode of lecturing, his papers and books, made a great impression upon my whole future life. As a private lecturer at the University of Prague, where I trained young teachers in physics, and some years after, as professor of experimental physics at the Technical High School at Brno, I tried to follow my great teacher.

The laboratory work in our physical institutions at Prague and Brno, the spreading of English scientific literature throughout our libraries, our new text-books of physics, for both colleges and high schools, and especially the progress in new editions of books of practical physics, show clearly how we in Czechoslovakia have followed Sir Joseph Thomson's inspiring example.

Twenty years ago my friend Dr Záviška, professor in the Bohemian University, worked at the Cavendish, and his scientific work and method of teaching through these years are proofs of the inspiring guidance of the great director of the Cavendish Laboratory.

I am very happy to send this modest message of our deepest thanks, and appreciation of Sir Joseph Thomson's influence upon the progress of physical science in our country, on the occasion of the celebration of his seventieth birthday.

Prof. KARL PRZIBRAM,

Radium Institute, Vienna.

While deeply indebted to the editor for giving me the opportunity of joining in the world-wide chorus of congratulation in the columns of NATURE, I should feel abashed if it were not possible for me to say that I am "a citizen of no mean city"—the city of Doppler and Loschmidt, of Stefan and Boltzmann.

It is obvious that a centre of learning that boasts of such names on its roll of honour would offer fertile ground for the new ideas so lavishly given to the world by Sir J. J. Thomson. Yet, apart from certain researches on ionic mobility and condensation, which were, so to say, imported directly from Cambridge, this Thomsonian influence on Viennese science is difficult to trace in detail, not because it is too slight, but, on the contrary, too universal; it is, to-day, all-pervading, like the air we breathe.

To the world of science in general, J. J. Thomson stands out as one of the great pioneers who, beginning in the last decades of the nineteenth century, blazed the trail for the new physics. But to the awe and veneration due to such a leading genius there is added for those who, like myself, were privileged to enjoy the genial hospitality of the Cavendish Laboratory years ago, a warmer, more personal feeling: it is the yearning for those unforgettable old days in Cambridge and for that band of inspired workers with J. J. Thomson as their centre.

Prof. A. SOMMERFELD, For.Mem.R.S.,

University of Munich.

May I be permitted to mention an activity of Sir J. J. Thomson's which has almost been lost in the shadow of his later brilliant successes, but nevertheless constitutes a characteristic feature in the record of this investigator; I refer to his "Recent Researches in Electricity and Magnetism"—the so-called third volume of Maxwell. He is dealing here with the good old mathematical physics, the actual formal treatment of special physical problems. Both in Maxwell's "Treatise," and in J. J. Thomson's continuation of it, these are found in equilibrium, so to say, with the new and specifically Maxwellian ideas, but in recent times they have been in danger of being suppressed under the weight of modern interests. It was thus that J. J. Thomson at first continued the great school of mathematical physics which arose in Cambridge under Green and Stokes. In this way he laid for himself and his students the solid foundations on which the researches on the electron could be built.

Modern physical theories are transient, the mathematical methods eternal; if they seem temporarily to be asleep, they revive again in previously unsuspected regions. This is illustrated in the theory of relativity, where the Riemann geometry suddenly sprang into physical life, and it is now illustrated in the quantum theory, which has recently come under the sway of the boundary condition problems of classical mathematical physics.

We hope that the physics of the future will not be lacking in men like J. J. Thomson, masters at once of physical problems and mathematical methods.

Prof. P. ZEEMAN, For.Mem.R.S.,

University, Amsterdam.

"*From the point of view of the physicist, a theory of matter is a policy rather than a creed; its object is to connect or to co-ordinate apparently diverse phenomena, and above all to suggest, stimulate, and direct experiment.*" —J. J. Thomson, "The Corpuscular Theory of Matter," p. 1, 1907.

The invitation to contribute a message to NATURE on the occasion of Sir J. J. Thomson's seventieth birthday, is one which I gladly accept, though I realise how difficult it will be to formulate in a few lines the feelings of admiration Sir Joseph's influence on physical science provokes in all parts of the world where science is flourishing. Whenever any one personally acquainted with Sir Joseph reads his name, they see in their mind's eye his powerful head and characteristic appearance, inspirations for an artist on various occasions.

It is a delight to inspect the photographs taken from time to time in the Cavendish Laboratory during J. J. Thomson's tenure of the directorship and representing the professor surrounded by his research students. The influence Thomson has exercised upon his generation is nobly illustrated by these pictures. It is remarkable that so many of his former pupils are now filling important posts in other learned institutions and that several of them are in the very first rank of physicists. The photographs honour the great teacher, and at the same time set in a clear light the exceptional ability of the British mind to see the root of things.

A paper of great importance, "On the Electric and Magnetic Effects produced by the Motion of Electrified Bodies," appeared in 1881. Thomson showed that the magnetic field set up by an electrified particle in motion increases the apparent mass of the particle. Indeed, he gave us the first formula for the electro-dynamic mass The investigation is a most remarkable example of early genius, its author being at the time only twenty-five years of age. Unintentionally, Thomson was preparing himself for his grand work on the true nature of the cathode rays and the isolation of the electron.

The profound mathematical insight of Thomson we can admire in his "Applications of Dynamics to Physics and Chemistry," published 1885–1887, forerunner of Hertz's "Prinzipien der Dynamik," written at a time when the mirage of a real kinetic theory of matter was firmly believed in.

Before the last-mentioned investigations were published, Thomson was giving a great deal of his attention to experimental work in the laboratory, and apparently he did so more and more. Thomson's papers reveal the talents of the experimenter and of the mathematician, combined in a most remarkable and happy way. Unfortunately this combination, which enables their possessor to penetrate into the hidden depths of Nature, is very rare.

During a period of forty-five years, the results of Thomson's restless mental activity and originality have been given to the world in a series of investigations happily summarised in several books published as the subjects became ripe for description. They all exhibit the clearness and conciseness which are characteristic of Thomson's writings. I refer here not only to the fundamental work on the "Conduction of Electricity through Gases," but also to the delightful smaller books "The Discharge of Electricity through Gases"; "Electricity and Matter"; "The Corpuscular Theory of Matter"; and "The Electron in Chemistry"

Thomson's researches are often directed on questions relating to the deep and hidden nature of matter and electricity. He counts the number of electrons in the atoms; he arranges with his fertile imagination the electrons in coplanar rings inside a sphere of positive electricity; he gives us suggestions toward the explanation of the periodic law of the chemical elements; he gives us his views on the structure of light, and boldly explains some great difficulties of the old wave theory by his speckled wave front. A charming episode in the midst of these difficult investigations is the discovery of the isotopes of neon by Thomson's parabola method.

We hope that physics may still for many years benefit from Sir J. J. Thomson's labours.

Prof JOHN ZELENY,

Yale University, New Haven, Connecticut.

Science knows no national boundaries. An important discovery made in one laboratory soon becomes common knowledge and has its stimulating effect upon investigators throughout the world. The influence of any individual scientist upon research work in countries outside of his own is dependent therefore to a large extent upon the pioneer character and importance of his investigations. Greatly indebted as physical research in the United States is to Sir Joseph Thomson on such grounds alone, there are special reasons why his influence has been even greater than this measure would indicate

In the first place, during Sir Joseph's incumbency of the Cavendish professorship at Cambridge, physical research in the United States expanded enormously and spread to many institutions where previously little or none had been done. The inspiration that produced this growth was supplied in part by the few centres in our country where research was already thriving, and this influence must not be under-estimated. But the eyes of the scientific world were upon Sir Joseph and the Cavendish Laboratory, because from this source in rapid succession new ideas were being brought to light that were making a very deep impression on scientific thought. It was inevitable that this activity should spur men on to do research work and to choose as the field of their endeavour the one that was yielding such remarkable results.

Another important channel through which Sir Joseph's influence was disseminated in the United States was through those of our men who in this period worked under his direction in the Cavendish Laboratory. Many of these men already held influential positions in our universities, and on returning imparted to an increasing circle the enthusiasm for research which they had absorbed at the fountain-head.

Mention must be made, too, of the beneficial effect upon our research men of Sir Joseph's visits to the United States and of the lectures he gave there. Large numbers were thus not only able to hear him explain his most recent theories but also to benefit greatly from an intimate discussion with him of their own problems

Those of us who had the rare privilege of working with Sir Joseph at the Cavendish Laboratory count the years spent there as among those that we cherish most. We lived in an atmosphere sparkling with new thought. We enjoyed a free and happy comradeship. New ideas and interpretations of experimental results had to stand the test of friendly but none the less vigorous criticism. We experienced the thrill of being present when important discoveries were in the making, and day by day we were permitted to observe the working of Sir Joseph's penetrating and resourceful mind

Over and above all is the fact that this great man is wonderfully human. One cannot forget his many interests, his kind heart and lovable nature, his humour, the cheerfulness he radiates, his hospitality, and his readiness to serve others. To know him is to have for him a reverence and affection that but grows with the years.

The Jolly Electron.

Sung to the Tune of "The Jolly Miller," at the Physical Society Club.

1. There was a jolly electron—alternately bound and free—
Who toiled and spun from morn to night, no Snark so lithe as he;
And this the burden of his song for ever *used* to be:—
"I care for nobody, no, not I, since nobody cares for me."

Chorus.

And this the burden of his song for ever *used* to be,
"I care for nobody, no, not I, since nobody cares for me."

2. Though Crookes at first suspected my presence on this earth,
'Twas J. J. Thomson found me—in spite of my tiny girth.
He measured first the "e by m" of my electric worth;
I love J. J. in a filial way, for he it was gave me birth!

Chorus.

But this the burden of my song, etc.

3. 'Twas Johnstone Stoney invented my new electric name,
Then Rutherford, and Bohr, too, and Moseley brought me fame;
They guessed (within the atom) my inner and outer game,
You'll all agree what they did for me,
I'll do it for them, the same!

Chorus.

But this the burden of my song, etc.

4. Then Wilson, known as 'C. T. R.,' his camera brought to bear,
And snapped me (and the Alphas too) by fog-tracks in the air.
We like that chap! For a camera snap is a proof beyond compare;
A regular star is C. T. R., we'd follow him anywhere!

Chorus.

But this the burden of my song, etc.

5. So whether I rest as static charge, or rove in the ether free,
Or whether I settle in nuclear state, perched up on a proton's knee,
Or whether I spin my quantum yarns, in a spectroscopic key,
I'll love the 'Physicals' all the time, since all of 'em dote on me.'

Chorus.

But this the burden of my song for ever *used* to be,
"I care for nobody, no, not I, since nobody cares for me."

R. A. S. PAGET.

The Cavendish Laboratory as a Factor in a Counter-Revolution.

Sir NAPIER SHAW, F.R.S.

NOW that Parliament in its wisdom has once more made the University of Cambridge responsible for the teaching of its students, the wheel has come round full circle and we may fairly indulge in a retrospect about the teaching of science. The story may begin with 1851, when reforms were introduced largely at the instance of the Prince Consort, who had been elected Chancellor in 1847. There is an early pencilling in *Punch*, by John Leech, representing the election day with a placard of the opposition "Boats no Botany." It is astonishing how placidly an undergraduate can go through his course unconscious of living in a time of momentous change. The final statutes for the University of the 1851 Commission are dated 1858; but for the first time, in 1851, the class lists record the results of a Moral Sciences Tripos and a Natural Sciences Tripos, both quite new. Previously, dating back to 1824, there had been a Classical Tripos; but before 1851 it was limited to candidates who had already obtained honours in the Mathematical Tripos. The published class lists of that educational instrument go back to 1747–48 and form the connecting link between the triposes* of to-day and the academic system of the Middle Ages when the University was paramount.

In my undergraduate days there were still some notable relics of that system. Within the structure of the central University building, the Library, there were a Divinity School, a Law School, and an Arts School, each arranged like a court of justice. There was a Medical School also; but already it possessed a separate building with a museum and dissecting-room.

The schools were originally arranged for the candidates for honours to 'keep' their 'acts' for degrees in the faculties of Divinity, Law, Arts, and Medicine, with moderators for judges, proctors for police, and University students for the general public. The candidate sat upon his tripos as proponent of a thesis in theology, law, medicine, or philosophy, with opponents to take sides in a public disputation. That had been the medieval plan for deciding upon the relative merits of the candidates. Since the beginning of the sixteenth century there had been Regius professors in divinity, law, and physic, who could act as moderators for their faculties. There was also a Regius professor of Greek who might have been regarded as dean of the general faculty of arts or philosophy; but the colleges had captured the right of moderation in that faculty before the end of Queen Elizabeth's reign, and moderators were nominated by the colleges in turn, according to a fixed rota.

The colleges had also assumed responsibility for the education of their students in preparation for the final act The University had only to decide the relative merits of the candidates from different colleges. It accepted for matriculation, without examination, the candidates presented by a representative of a college in person. The colleges had their own curricula and provided their own teaching upon which they based their right to certify candidates as worthy of degrees.

The college curriculum was still in vogue in my time; it consisted of lectures on classical and mathematical subjects which were combined in one annual examination upon the results of which prizes were awarded. The subjects were in fact selected with an eye to the University examinations, which at that time and developed into a system. Physical science formed no part, except in so far as physical subjects were included in the comprehensive subject of mathematics.

It must be remembered that what was called mathematics in the third quarter of the nineteenth century was the direct successor of the arts or natural philosophy of the schoolmen. Latin was the language of the arts, and the colleges taught Latin. There was no professorship of Latin in the University until 1869. From 1663 there was a Lucasian professor of natural philosophy. Isaac Barrow was the first, Newton the second. From 1680 there was a professor of moral philosophy. Before the end of the eighteenth century there were in addition two professors of astronomy, professors of chemistry, modern history, Arabic, botany, geology, and natural and experimental philosophy, all of whom may have looked to the curriculum in arts for their students.

With the development of mathematics after Newton, 'arts' became concentrated in natural philosophy. The Act in the schools gave insufficient scope for adequate testing and a written examination was instituted, which carried off the name of the tripos and became the Mathematical Tripos; but when I was introduced to it its range was by no means restricted. It included statics, dynamics, hydrostatics, optics (geometrical and physical), spherical astronomy, lunar and planetary theories, hydrodynamics, sound, waves and tides, elasticity, heat, electricity, and magnetism. The last three were in a sense new; the University had restored the original comprehensive range of natural philosophy by adding them as additional subjects, and appointed an additional examiner for them. James Clerk Maxwell was the first.

Thus the range was very wide; but the teaching was not coterminous with the subjects named. From the nature of the examination, it became limited to the mathematical extracts from the original contributions of accepted authorities. There were, in fact, in the colleges some survivals of an experimental method in the shape of an unused skeleton or the residue of an Atwood's machine; but the philosophy and history of the sciences were disregarded. I remember an example. We had to be examined in thermodynamics. P. G. Tait had written a book about it. Tait was a first-class talker and disputant; his book has three chapters; the first two were interesting and polemic, the third was thumb-nail mathematics. We were instructed to confine our attention to the third—to 'cut the cackle' and come to the differential equations.

Thereby I am reminded that in the period from 1865 until 1875 there was an effervescence of text-books in pure and applied mathematics, the like of which can never have been seen before or since. They were mostly bound in green, and judging from the survivals in my own library, the firm of Messrs. Macmillan and Co. must have been mainly responsible for the output. It was also a period of the greatest exaltation of the private tutor, in connexion with which the names of Hopkins and Routh will be remembered. Routh had an astonishing faculty for enabling pupils to absorb the mathematical juice of the great crop of text-books, so that the amount of information appropriated in the course of three years is now almost beyond belief. To those of us who had some experience of practical physics and chemistry at school or at home it was an invaluable discipline. What it could mean to those who had not, I cannot guess.

Then came Nemesis. The University, or somebody else, realised that all this tremendous appropriation of the mathematical secretions of the workers in natural philosophy without any experiment was not exactly healthy. There was indeed a chemical laboratory, and the Lucasian professor at the time was an experimentalist, so was the Jacksonian professor; but practical astronomy in my experience was one visit to the Observatory to be shown the adjustments of the transit instrument and the mural circle—we might be asked about those in the tripos, but not about stars.

The new idea of restoring the experimental study of natural philosophy found expression by the Duke of Devonshire, Chancellor of the University, in the foundation of the Cavendish Laboratory Michael Foster had been brought to Cambridge by Trinity College about the same time as prælector in physiology, and a laboratory was found for him somewhere.

The early days of the Cavendish Laboratory were of peculiar interest. People who have since distinguished themselves worked there at their leisure: George Chrystal, Sir Donald MacAlister, W. M. Hicks, Sir Arthur Schuster, and Sir Richard Glazebrook. There were lectures by the professor and more elementary lectures by his demonstrator, W. Garnett; but there were no practical 'classes,' though the Natural Sciences Tripos included a practical examination. So the last quarter of the nineteenth century may indeed be aptly called the age of the practical class in science. Any one who visited the University now would scarcely suppose it possible that fifty years ago there were no classes in practical work.

It may perhaps be said now that there are too many; and indeed it is scarcely an exaggeration to write that the only thing to do with any system of education that has become established is to change it. No plan can be permanently successful; at least no scheme of examination can be.

Sir Richard Glazebrook and I made a text-book and, as we thought, a very good one. It was designed to enable a class of students to inform themselves about the physical nature of things by using different aggregations of the miscellaneous collection of apparatus at the Laboratory.

I sometimes wonder how many of those experiments we had ourselves performed when we described them in such detail. But with the examination before them, our students and their successors have insisted on doing them all, and perhaps from their point of view they were right; but the result is wrong. The experiments were designed and described as a short cut to something better.

Nevertheless, the practical work in science, of which the Cavendish Laboratory is typical, furnished demonstrations not only of experimental physics but also of the University's care for teaching. The example has been followed, expanded, and improved until this term, under the new statutes, the University has recaptured from the colleges the right to teach its students the arts, as well as divinity, law, and medicine, a right which it surrendered in the spacious days of Queen Elizabeth.

News and Views.

PHOTOGRAPHS of the 'Pithecanthropus skull' recently obtained at Trinil in Java by Dr. Heberlein have now been received by Dr. Dubois of Haarlem. At the time of the discovery it was positively announced to be of the pithecanthropus type, but Prof. Elliot Smith has received a cablegram from Dr Dubois in which he says, "Photographs received show *caput humeri stegodon*" The second pithecanthropus skull thus turns out to be a pleistocene elephant! Much disappointment will be felt at this pronouncement, which, however, does not come entirely as a surprise. The information received in England from America soon after the first announcement made it clear that the discovery was not likely to prove so important as at first indicated The more complete statement of the character of the find and the conditions in which it was obtained—it was not found *in situ* as at first stated, but was obtained from the inhabitants of the village, and it was also said not to be a complete skull—pointed to the need for suspending judgment on the importance of the find. The wide publicity given to the discovery serves to emphasise the dangers of over-hasty dissemination of news through the ordinary channels of the press without effective and well-informed supervision such as might be afforded through the medium of a centralised scientific news service

THE RIGHT HON. NEVILLE CHAMBERLAIN, Minister of Health, presided at the reopening ceremony of the Wellcome Bureau of Scientific Research and the Museum of Medical Science on December 8. In the unavoidable absence abroad of the founder, Mr. Wellcome, Dr C M. Wenyon, Director of the Bureau, received the guests. Mr Chamberlain, in the course of his remarks, dwelt on the great advances made by medical science in the course of the last century, largely due, in his opinion, to the improvement in the means of imparting knowledge to those interested throughout the world. He considered that the motive actuating Mr. Wellcome in founding the Bureau was a conception of the two greatest factors which help mankind to overcome the infirmities to which all, in some degree or other, are subject; these two factors are research and education. Research is carried on not only at the Bureau, but also at the Wellcome Physiological and Chemical Research Laboratories; education is subserved by the Museum of Medical Science, to which all interested are welcomed, where, moreover, teachers are permitted to give demonstrations to their students.

SIR WALTER FLETCHER, Secretary of the Medical Research Council, followed Mr. Chamberlain with an address on "Research and Citizenship." After referring to the admirable scientific work of the staff of the Bureau, he turned to the consideration of the means by which research has been in the past and is at present financed Many brilliant investigators have been enabled to pursue their work owing to the accident of possessing private means or owing to the liberality of some friend or private institution. It is only within the last twenty-five years that the State has made grants in aid of research work, with the establishment of such institutions as the National Physical Laboratory in 1900 and the Medical Research Council (then a Committee) in 1913. Business firms have forwarded scientific work in three ways. Private fortunes made in commerce have been devoted to the endowment of research. Manufacturing firms have set up their own research laboratories; and although the investigators are not always free to publish the results of their work, yet the public are indirectly benefited by the increased efficiency of the firms in question. Finally, a few firms have adopted the plan of setting up research laboratories and leaving the workers as free to follow their own line and publish their results as men in any university laboratory. In Great Britain, the Wellcome Bureau is an example of the latter method of endowing research; abroad, the work of Langmuir and Coolidge in America and of Sørensen in Copenhagen has been made possible by similar endowments from commercial firms. The proceedings were terminated by Mr. Chamberlain declaring the Bureau and Museum open, and the guests then accompanied him and Dr. Wenyon on a tour of the halls and laboratories.

IN an address on "International Interests in Raw Materials" to the Royal Society of Arts, which is published in the Society's *Journal* for November 26, Sir Thomas Holland laid stress on the importance, for economic as well as military reasons, of making a precise estimate of the mineral resources of the British Empire A large number of minerals are essential for the maintenance of civilisation, and many of them cannot be replaced in the functions for which they are used. Minerals are wasting assets, and their consumption is annually accelerating to such an extent that a partial famine for some important substances will confront the next generation. The United States has recently inaugurated a systematic inquiry into its stocks of essential minerals on lines of precision and thoroughness that will leave little doubt as to resources available. For the British Empire the matter is at least of equal importance. The Mineral Resources Bureau collects figures of production and movement, but that is a small part of the problem. To make a complete or even partially complete survey, private sources of information must be tapped. The specialist in the course of his professional practice must have acquired information which, in the aggregate, would be of immense value even if the results were published only as totals for each considerable section of the British Empire.

ON October 27, Dr. R. J. Tillyard, chief of the Biological Department, Cawthron Institute, Nelson, New Zealand, delivered the Trueman Wood lecture before the Royal Society of Arts, upon "The Progress of Economic Entomology (with special reference to Australia and New Zealand)"; and this is published in the *Journal* of the Society for November 12. Dr. Tillyard points out that the main problem of economic entomology is how to intervene scientifically, in the most successful manner, in order to prevent the huge losses caused by insects to man's food supply and forests. The past thirty years have witnessed an immense development of what we may term the chemical method of attack, and the technique of the latter has been revolutionised during the last few years, particularly in America. Special reference is made to the commercial use of aeroplanes for dusting large areas of vegetation, and Dr. Tillyard expresses the hope that Great Britain will not be long in following Germany and Russia, which have already conducted promising trials with regard to the possibilities of this new line of attack. He deals very fully with biological control and emphasises the fact that three organisms are involved in the problem, namely, (1) the plant, (2) the insect attacking the plant, and (3) the parasite or predator of that insect. Occasionally we have also to consider secondary or even tertiary parasites of the parasite or predator.

THE possibilities of biological control are being explored in Australia and New Zealand, and the recent very striking success achieved by the introduction of the Chalcid parasite ***Aphelinus mali*** from North America into New Zealand, for controlling the woolly aphis of apple, is an example of it. The re-exportation of this same parasite into Australia is also proving highly beneficial in the latter country. The biological control of imported weeds which have so far resisted all other means of eradication is also discussed. The possibilities of introducing insect enemies of such weeds from their countries of origin into lands where the weeds have become established are worthy of the fullest exploration. Experiments of this nature, however, need to be carried out with adequate safeguards, under expert guidance, lest such insects turn their attention to cultivated plants and thereby become new evils rather than benefactors as originally intended. The work that is being carried out in Australia on prickly pear control by means of introducing Opuntia-feeding insects to prey upon that plant is particularly noteworthy. It appears that this problem is nearer solution than hitherto by means of the biological control exercised by insect enemies on this formidable pest. The importance of attempting likewise the control of blackberry, gorse, and other noxious weeds in New Zealand through the utilisation of certain insect enemies is also stressed by Dr. Tillyard, and his scheme for meeting the problem is outlined.

THE League of Nations' Committee on Intellectual Co-operation has published an important memorandum by Madame Curie, the eminent physicist, on the question of international scholarships for the advancement of the sciences and the development of laboratories. Madame Curie directs attention to the ever-increasing specialisation in the equipments and programmes of laboratories and the increasingly complex organisations of their staffs, and urges that fellowship and scholarship schemes should be so framed as to fit in with and take advantage of these conditions. To do so they must have due regard to two essential necessities: advanced workers, who have already made their names by scientific work, must be given the means of continuing their work; all candidates anxious to devote themselves for some time to science must be given a chance of developing their talents on the sole condition that they are recommended by their tutors or have obtained satisfactory university degrees.

WITH such a scheme, a complete foundation would accordingly control scholarships of two grades: for research fellows and for probationary scholars (two or three times as many). It would, further, provide grants to laboratories amounting to perhaps a quarter of the amount of the scholarships, to enable them to meet the increase of expenditure resulting from increase in the number of workers. Each probationary scholar would be assigned by the director of the laboratory to one of the research groups in which a vacancy is expected. A research fellow would work independently on a subject chosen by himself with the approval of the director or set for him by the director. The memorandum concludes with proposals, which have been adopted by the committee, for an inquiry into national and post-graduation scholarships and the best means of organising a system of international scholarships. Lord Balfour's research sub-committee of the Imperial Conference might well devise and provide for financing some such scheme for minimising the obstacles in the way of interchange between research workers in different parts of the British Empire and so meeting, to some extent, the competition of the magnificently equipped and endowed laboratories in the United States for the best brains of the Empire.

IT is surprising that, notwithstanding the advances made in recent years in the study of phonetics and the methods of recording spoken sounds, there is still no agreement as to the form of script to be used in recording the spoken languages of India, although the question has often been discussed. With the example of America before us, it should be possible for something to be done. In the United States a script has been evolved adequate to meet all the needs of recording a group of languages of considerable phonetic difficulty. The languages of India should present far fewer stumbling-blocks This question is again raised with special reference to the Munda group of languages by Mr. P. O. Bodding in the *Journal and Proceedings of the Asiatic Society of Bengal*, vol. 25, part 1, where he insists upon its urgency, now that changing conditions are beginning to affect the habits of the people. He quotes a number of errors which, as a matter of practice, arise through an imperfect method of recording the language, while from the scientific point of view the importance of an accurate method of recording the spoken sounds has been greatly enhanced by the extension of the comparative study of linguistics. A question of such moment as this would seem to call for action on the part of some influential body, such as the Asiatic Society of Bengal, before it is too late and these languages have been profoundly modified by contact with the outer world.

IN many physical theories—as, for example, in the atomic theory of gases or in J. J. Thomson's corpuscular theory of light—the theory of probability plays a leading part In a paper read by Mr. G F O'dell on December 2 to the Institution of Electrical Engineers on certain aspects of automatic telephone working, this theory is also largely used when discussing purely technical matters The problems considered were those arising when provision has to be made for more than one telephone call at one time. In automatic exchange working, when the caller removes his receiver, his 'preselector' hunts for a disengaged first selector. On his dialling the first digit, the first selector steps up to the corresponding level and then hunts until it finds an idle second selector. On the receipt of the second digit, the second selector rises and searches for an idle final selector, which in turn responds to the third and fourth digits. In addition to the subscriber being actually engaged, there are three places in this chain of events at which the call may be 'lost' or delayed In order to discuss the theory, telephone engineers find it convenient to define a 'telephone traffic unit.' This unit is the average number of calls in progress simultaneously during a specified period. It is simply a number and has no physical dimensions. One of the problems discussed by Mr. O'dell was the best method of arranging switching plant to the best advantage. This necessitates using the theory of probability. Another problem the solution of which forms the basis of the design curves in common use in the United States is to find the grade of the service. This is measured by finding the proportion of the traffic lost when a given volume of traffic, measured in traffic units, is offered to a definite group of switches. Mr. O'dell showed that telephone engineers fully realise the help that an advanced knowledge of mathematics can be to them. He also developed an analogy between 'trunking' problems and those which arise when discussing the performance of heat engines. It is thus shown how one branch of applied theory can help another.

THE present year marks the centenary of the founding of *Crelles Journal fur die reine und angewandte Mathematik* or Crelle's Journal, the oldest organ of mathematical research in Germany surviving to the present day. Of earlier mathematical journals, only the French *Journal de l'École Polytechnique*, founded in 1794, has enjoyed a longer period of continuous publication. The earlier volumes of Crelle were enriched by papers from Gauss, Abel, Jacobi, and Steiner, while many of the more distinguished Continental mathematicians have contributed to its pages in more recent years. Among Englishmen, Cayley, with eighty papers, was the most frequent contributor. It is the intention of the editors to celebrate the centenary worthily by issuing two commemoration volumes (157 and 158) in which will be shown, in the true perspective of distance, the part played by this journal in developing the science of mathematics during the last hundred years.

PROF. J H. PRIESTLEY, of the department of botany, University of Leeds, is to give a course of post-graduate lectures and demonstrations to students of the departments of botany and bio-chemistry of the University of Berkeley, California, during the spring of next year. Prof. Priestley will deal with the subject of developmental anatomy. His lectures will include some account of the work done in the botanical department at Leeds upon the structure, function, and distribution of the endodermis; the structural features associated with the phenomena of etiolation; and the problem of phototropism. Prof H. H. Dixon, of Trinity College, Dublin, has similarly been invited to lecture at the University of Berkeley in the summer months of 1927.

A SERIES of violent earth-shakes disturbed the Rand on the morning of December 7, and in the Wolhuter gold mine there were two rock-bursts which caused the death of four persons. The earth-shakes seem to be due to the collapse of the surface-rocks over disused mining tunnels In the early days of the mines, no earthquakes were noticed in the Rand, but in 1905 they began to occur and soon increased so much in frequency that in 1910 a seismograph was erected in the Johannesburg observatory. During the next fourteen years, 5427 local shocks were recorded. It was noticed that they occurred in series, and most frequently in the dry season. This led to greater care being used in timbering and re-filling abandoned tunnels, and during the last two years local shocks have decreased in number (*Volcano Letter*, October 31, 1926, issued by the Hawaiian Volcano Research Association).

THE seventeenth annual Exhibition of the Physical Society and the Optical Society to be held on Tuesday, Wednesday, and Thursday, January 4, 5, and 6, at the Imperial College of Science and Technology, Imperial Institute Road, South Kensington, will be open in the afternoon from 3 P.M. to 6 P M. and in the evening from 7 P.M. to 10 P.M. On January 4 at 8 P M. Prof. E. N. da C. Andrade will reproduce with contemporary apparatus a physical lecture of the early eighteenth century. On January 5 at 8 P.M. Dr. C. V. Drysdale will lecture on "Progress in Electrical Instrument Design and Construction," and on January 6 at 8 P.M. Mr. J. L. Baird will give a lecture on "Television." Some seventy firms are exhibiting apparatus, and in addition there will be a group of non-commercial exhibits, including demonstrations of famous historical experiments in physics, recent research and effective lecture experiments. Tickets, which can be obtained from the secretaries of related scientific societies or direct from Prof. A. O. Rankine, Imperial College of Science and Technology, South Kensington, S.W.7., are required for January 4 and 5, but on January 6 the Exhibition will be open to the general public without tickets.

THE issue for November 15 of *Power Plant Engineering* contains a short illustrated account of the remarkable high-voltage laboratory erected at Stanford University, California. The laboratory has been erected by the University with the aid of some of the big electrical firms to ensure the continuance of the research work of Dr. Harris J. Ryan. The main building of the laboratory is 173 feet long, 60 feet wide, and 65 feet high, and in this are installed the six specially designed transformers, each of which is rated at 350,000 volts high tension, 2300 volts low tension, and each of which weighs 22 tons. These have been constructed so that they may be used in every manner of connexion for the whole range of voltages single-phase or three-phase, up to 2,100,000 volts single-phase and 1,200,000 volts three-phase. The work of the laboratory was inaugurated on September 17, when before an assemblage of men of science a 2,100,000 volt spark was discharged between points 20 feet 1 inch apart.

WE much regret to record the death, on December 11, of Sir William Tilden, F.R.S. Sir William, who was formerly professor of chemistry and dean of the Royal College of Science, London, and emeritus professor in the Imperial College of Science and Technology, South Kensington, had reached the age of eighty-four years.

LORD D'ABERNON has accepted the chairmanship of the Industrial Fatigue Research Board, to which he has been appointed by the Medical Research Council. Mr. William Graham has relinquished the chairmanship of the Board under the pressure of other public work, but will remain a member of the Board.

IT is stated in *Science* that Prof. J. J. Abel, professor of pharmacology at Johns Hopkins University, is to receive the Willard Gibbs gold medal for 1926 awarded by the Chicago section of the American Chemical Society. Prof. Abel's work has been largely in the field of glandular extracts; he isolated epinephrin as a pure crystalline body from the suprarenals, and recently he has announced the preparation of insulin in crystalline form.

IT has now been decided to close the fund raised to signalise the long services of Prof. A. G. Perkin to science and to the University of Leeds. Prof. A. G. Perkin, it will be remembered, has recently retired from the chair of colour chemistry and dyeing. Those who desire to be associated with the purpose of the fund are asked to send their subscriptions to Prof. A. F. Barker, The University, Leeds, at an early date.

THE twenty-fifth anniversary of the historic wireless experiments conducted by Senatore Marconi between the Poldhu wireless station in Cornwall and St. John's, Newfoundland, which resulted in the transmission and reception of wireless signals between the old and the new worlds for the first time, fell on Sunday, December 12. Senatore Marconi's achievement in 1901, only six years after his earliest experiments at his father's house in Bologna, Italy, marked an epoch in the development of wireless communication and firmly laid the foundations of the long-distance wireless communication which to-day covers the whole world.

THE following lecture arrangements at the Royal Institution before Easter next year have been announced. The Christmas Course of six lectures for juveniles will be delivered by Prof. A. V. Hill, on "Nerves and Muscles: How we Feel and Move," commencing on December 28 at 3 P.M. On Tuesdays, at 5.15 P.M., beginning on January 18, there will be two lectures by Prof. R. Whytlaw-Gray on smokes as aerial disperse systems, six by Prof. Julian Huxley on problems of animal growth and development, two by Dr. G. Shearer on X-rays and the chemical molecule, and two by Prof. J. W. Cobb on some properties of coke. Thursday afternoon lectures, at the same hour, include three lectures by Sir William Bragg on acoustical problems treated by Lord Rayleigh; three by Prof. John Garstang on the progress of Hittite studies; two by Mr. J. Guild on colour measurement and standardisation; and two by Mr Harold J. E. Peake on the beginnings and early spread of agriculture. Saturday afternoon lectures at 3 P.M. include four by Sir Ernest Rutherford on the α-rays and their application to atomic structure. The Friday evening meetings will begin on January 21, when Sir William Bragg will deliver a discourse on Tyndall's experiments on magne-crystallic action. Succeeding discourses will probably be given by Prof. E. P. Cathcart, Mr. T. L. Eckersley, Dr. Ernest Law, Sir Josiah Stamp, Prof. D'Arcy Thompson, Sir Herbert Jackson, Dr. George Macdonald, Mr. E. Hatschek, Prof. C. T. R. Wilson, Sir Ernest Rutherford, and other gentlemen.

WE have received the annual report of the Laboratory of the Joint Board of Research for Mental Disease, City and University of Birmingham, of which the late Sir Frederick Mott was honorary director. Determinations of the iodine content of the thyroid gland have been made in various conditions, and show that septic infection and tuberculosis cause considerable variation. Investigations have been pursued on basal metabolism in conditions of conscious and unconscious contraction and relaxation of muscles, on changes in the central nervous system as a result of the administration of hypnotic drugs, and on the permeability of the membranes of the brain to the bromine ion after administration of sodium bromide.

THE topographical survey of the colony of Sierra Leone is at length to be put in hand. Up to the present no satisfactory map of this part of British

Africa has been available. A year ago the financial position of the country justified the formation of a new survey department, of which the first annual report has now appeared. It has been decided to aim at a one-inch scale for the whole colony, which will entail 111 sheets. A start is to be made in the central and southern parts of the Northern Province. A school for training native surveyors has been started, but in order not to delay the work, trained surveyors have been temporarily transferred from the Gold Coast. A large scale cadastral survey of Freetown is in hand and well advanced.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A research student at St. Mary's Hospital Institute of Pathology and Research—The Secretary of the Institute, St. Mary's Hospital, Paddington, W.2 (December 20). A research assistant in the Department of Pharmacology of the University of Sheffield, to help in an investigation on cancer, and a laboratory attendant with experience of physiological or pathological and chemical technique for the same institution—Prof. E. Mellanby, The University, Sheffield (December 22). A demonstrator in chemistry at Guy's Hospital Medical School—The Dean, Guy's Hospital Medical School, London Bridge, S.E.1 (December 29). An adviser in agricultural chemistry in the University of Manchester, under the scheme of the Ministry of Agriculture and Fisheries—The Registrar, The University, Manchester (January 20). Lecturers in organic chemistry, physical chemistry, and biochemistry at the Indian Institute of Science, Bangalore, India—The Director (January 30). A professor of physiology in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (January 31). A senior lecturer in philosophy in the Transvaal University College, Pretoria—The Registrar, Transvaal University College, Pretoria (January 31). A professor of anatomy in the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (February 26). A professor of philosophy at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (March 12).

Our Astronomical Column.

THE COMET GRIGG-SKJELLERUP.—Mr. G. Merton read a paper on this comet at the meeting of the Royal Astronomical Society on December 10. The identity of the comet found by Skjellerup in 1922 with that found by Grigg in 1902 was first suggested by Crawford and Meyer. Mr. Merton has made it a practical certainty. He gets practically the same mean motion in 1922 from the observations in that year alone (they extended over three months, so the value is trustworthy) as by combination with those of 1902. The comet is due to return to perihelion on May 10, 1927; Mr. Knox Shaw is now searching for it with the large reflector at Helwan. It may be expected to be found not later than February. It approaches within 17 million miles of the earth in June; Comet Pons-Winnecke makes a still nearer approach (some 4 million miles) near the end of June.

INTERNATIONAL LONGITUDE DETERMINATIONS.—Dr. J. Jackson gives in the *Observatory* for November an interesting account of the extensive scheme of longitude determination by radio signals which has been in progress during October and November.

The observatories of Algiers, Shanghai, and San Diego (California) form the principal chain, but some fifty other observatories are co-operating. The use of travelling wire micrometers practically eliminates personal equation, and enables longitude differences to be determined without interchange of observers. Dr. Jackson obtained star observations on seventeen nights between September 27 and November 1, the transit instrument being reversed on each star to eliminate collimation. The Shortt clock has such a regular rate that its error can be interpolated for days without star observations. Thirty-four series of time signals are sent out daily from five stations; all except Saigon were regularly received at Greenwich.

THEORY OF SUNSPOTS.—An important contribution to the theory of sunspots and the sun's general circulation is made by Prof. V. Bjerknes in the *Astrophysical Journal*, September 1926, under the title "Solar Hydrodynamics." For the details of the theory reference must be made to the paper in question, but a short outline of the main points may be given as follows. On the assumption that a sunspot is a vortex decreasing in intensity from the photosphere downwards, their low temperatures are explained from general hydrodynamical and thermodynamical principles.

The results deduced are in accordance with the accepted temperatures of sunspots and the probable velocities of the gases involved in the vortex. A preliminary account of this part of Bjerknes' investigation was given in NATURE, March 27, p. 463. The well-known properties of sunspots (their usual occurrence in pairs having opposite magnetic polarities, the progression of the spot zones towards the equator during the 11-year cycle, the magnetic-polarity cycle of 22 years, etc.) are explained by making the following suppositions. In each of the sun's hemispheres, northern and southern, there are two zonal vortices, having opposite rotations and surrounding the sun approximately as parallels. Wherever part of either vortex rises and cuts the photosphere, a typical bipolar pair of sunspots makes its appearance. As part of a scheme of general circulation, these two zonal vortices revolve around each other in a period of 22 years, being brought alternately near to the surface of the photosphere in latitudes about 40°, progressing equatorwards in the course of 11 years, and descending again into the interior near the sun's equator. The scheme of general circulation is one demanding a condition of what is known as stratified circulation.

Renewed investigations are required on the part of observers to determine any possible systematic movements which may be shown by sunspots, faculæ, calcium and hydrogen flocculi, and prominences. The systematic drifts suggested by the theory are apparently too slow to be observed spectroscopically (cf. *Astrophysical Journal*, **32**, 80, 1910, where St. John compares the mean wave-length of K_2 and K_3 near the sun's poles and at the equator for detection of systematic movements).

Prof. Bjerknes' paper is also discussed, together with remarks bearing on the question of observed systematic motions of spots and faculæ, by 'W. M. H. G.' and 'H. W. N.' in the *Observatory* for December.

Research Items.

THE VALUE OF TRADITION.—In the course of a discussion of the value of tradition in Polynesian research, which appears in the *Journal of the Polynesian Society*, vol 35, No 3, Dr P. H. Buck (Te Rangi Hiroa) gives some remarkable examples of the manner in which Maori traditions are corroborated from outside sources, legendary and other. The Maori tradition states that their ancestors made voyages between the Sandwich Islands and their own Hawaiki or Tahiti of the Society group The traditional sailing directions from Ahuahu (Oahu, Sandwich Islands) to Aotearoa (North Island, N.Z) give a bearing south from Maui-tahu and Maui-pae to Hawaiki and from Hawaiki to New Zealand a little to the right of the setting sun In Hawaiian tradition in the directions for the voyage to Tahiti, the North Star is left directly astern. Further, Maui-tahu and Maui-pae are probably the twin islands of Lanai and Kahoolawe, Hawaiian tradition makes Ko-ola-i Kahiki the point of departure for Hawaiian voyagers to Tahiti, and this has been identified as a point on Kahoolawe Even more striking is the evidence of the magic calabash Hawaiian voyagers to Tahiti on passing the equator lost the North Star and picked up the Southern Star On their return they picked up the Northern Star and sailed in a north-easterly direction (owing to the prevailing wind) until they judged the star was the same height as in Hawaii. They then turned and sailed due west, checking the height of the star each night, in the early days no doubt by eye, but later by the magic calabash This calabash was fashioned into a primitive form of sextant with which the star was sighted on an elevation determined in Hawaii. An examination of one of these calabashes has shown that it is mathematically accurate, the angle being 19°, and Hawaii being in lat. 19° N.

DEFORESTATION AT PUEBLO BONITO.—After six seasons' excavations on the important site of Pueblo Bonito in New Mexico, it is now possible to arrive at some definite conclusions as to the causes which led to the gradual decline and final abandonment of this once populous centre of prehistoric Pueblo culture The population, some twelve hundred in number, was agricultural, living on the produce of the fields, once fertile, but now barren According to a Bulletin of the Smithsonian Institution, the expedition of the National Geographic Society, under the leadership of Mr. Neil M. Judd, archæologist of the Smithsonian Institution, in the course of its excavations has found an ancient arroyo completely filled up which has been traced for a considerable distance Its original bed was found at a depth of 18 feet, and on it were fragments of pottery made during the third and greatest building period of the Pueblo Further, it appears that the inhabitants used pine logs to roof the 800 rooms of their great dwelling The nearest pine woods are at present forty miles away, but evidence was discovered that pine had at one time grown in the canyon. It may therefore be concluded that the present sterility of the soil was brought about by the destruction of the pine forests which once surrounded the site, baring the soil to wind and water and allowing the spring rains essential for the crops to drain off into the arroyo, which then became wider and deeper. The fertility of the fields then became less, and the population decreased owing to migration as the food supply diminished, until the twelve hundred inhabitants had dwindled to a few families. The increase in the number of defensive works in each successive building period suggests that marauding raids helped to drive the inhabitants from their homes The excavations of 1926 show that there were four main periods of construction covering a period of about a thousand years. Differences in architecture and pottery indicate that two distinct populations in friendly relation inhabited the site at one time Later arrivals of a more advanced culture made Pueblo Bonito the most famous and important settlement of the south-west, but they were the first to abandon the site.

DETERMINING THE SEX OF CARRIER PIGEONS.—I. Iwata (*Jour Coll Agr*, Imp Univ Tokyo, vol 73, No. 4, 1926) points out differences, which enable the sex of carrier pigeons to be distinguished at various stages of growth In very young birds (from the time of hatching to the 24th day) the dorsal rim of the cloacal opening is more developed than the ventral in the male, while in the female the reverse is the case In older birds, after they have left the nest to the time of pairing, the wall of the cloaca of the male exhibits six internal elevations, whereas in the female five elevations are present and the anus is seen close to the postero-median elevation In general, too, the opening of the male cloaca is more tightly closed than that of the female In adult birds (more than six months old) the cloacal opening of the male is usually pentagonal in outline, and at its centre is the anal opening, also usually pentagonal The adult female cloaca presents a more or less triangular opening, the external skin at the posterior border of the cloaca projecting into the cloacal space along the short base of the triangle. By this time, however, the general appearance and behaviour of the birds is usually sufficient to indicate their sex Another point of difference is that in birds more than 120 days old the male presents a whitish line along the median portion of the dorsal side of the beak, between the nasal protuberances, which is wanting in the female

NEMATODES FROM JAPANESE FROGS AND TOADS.—K. Morishita records (in vol. 1, No. 1, Section 4 (Zoology), *Jour Fac Sci.*, Imperial Univ. Tokyo, 1926, which is a continuation of *Jour. Coll. Sci.*, Imp Univ. Tokyo) eight species of nematodes found during the examination of about a thousand frogs and toads. These nematodes include a new species of Hedruris, the female of which adheres to the wall of the duodenum of frogs and the spiral turns of the body of the male envelop the female; a new species of Spiroxys also from the duodenum of frogs (the genus Spiroxys has hitherto been recorded from tortoises); and a new species of Spinitectus from the stomach of *Rana nigromaculata*, the four previously known indubitable species of Spinitectus having been found only in fresh-water fishes of Europe and America.

GROUPING OF FORMS IN SCENERY.—In a paper in the *Geographical Journal* for November, Dr. Vaughan Cornish discusses the conditions of harmonious grouping in natural landscape and illustrates his theme from various aspects of scenery by land and sea. The reason for rearrangement, or composition, which the landscape painter adopts, arises largely from the fact that disharmonies of form occur in purely natural scenery, and the eyes find perfect satisfaction in the landscape only when there is a broad angle of outlook free from obtrusive disharmony. Dr Cornish points out that the generally expressed opinion that purely natural surroundings are always harmonious is due to the co-operation of the senses From descriptions of several mountain views he shows that ranges of the Alpine type provide the finest forms of mountain skyline The roughly pyramidal peaks are of sufficient size to appear important at the greatest distance at which atmospheric conditions allow visibility On nearer approach, the distant view of a row of pyramids gives place, as a rule, to a pyramidal complex bending upwards to a culminating peak: yet nearer, this vanishes and is replaced by a number of visually independent pyramids. The eye always finds harmony in the pyramidal form. Other features of scenery are discussed in this interesting paper.

PLEISTOCENE PLANTS FROM NORTH CAROLINA.—The study of Pleistocene plants has not made so much progress in America as in Europe, but Dr. E. W. Berry has recently made an interesting and important contribution to the subject (*U.S. Geol. Survey Prof. Paper* 140-*C*, 1926, p. 97) Beautifully preserved plant remains have been found in three (Wicomico, Chowan, Pamlico) of the five terrace plains which can be traced for long distances along the Atlantic coast of North Carolina and the adjoining States. The species recognised number 48, including two conifers, the remainder being Angiosperms; 11 are classed as extinct species new to science, several of these being regarded by the author as doubtful, but he feels confident that two or three are definitely new. The most abundant forms are the bald cypress, river birch, beech, various oaks. More than half are plants living in wet habitats, and may represent elements of the vegetation of estuary streams. None of the species can be regarded as a definitely northern form, though the terrace deposits contain boulders of considerable size which may have been brought down by river ice. On the other hand, the present distribution of some of the species suggests that the climate may have been somewhat milder than at present. The author considers that the present major floristic regions of North America were already well marked at the end of the Tertiary period, and he adds a map illustrating his views on the probable directions of post-glacial plant dispersal.

UPPER WIND VARIATIONS—A Memoir entitled "The Variance of Upper Wind and the Accumulation of Mass," by Mr. Lewis F. Richardson, Mr. Denis Proctor, and Mr. Robert C Smith, vol 1, No. 4, has just been issued by the Royal Meteorological Society (price 2*s* 6*d*. to non-fellows of the Society). The memoir contains a collection of statistical facts concerning deviations of wind from its mean The distances range from 1 km. to 100 km., deviations so large as or larger than gusts and smaller than cyclones. The effect of height on the variation is said to be very different in different circumstances, but on the average it is not much changed with height Morning and afternoon in summer have different variances, that in the afternoon being usually much the greater, when the stations were 11 km. or 12 km. apart, but at 28·5 km. separation the distinction was not clear. The greater variance on summer afternoons is explained as an effect of the increased turbulence due to the decreased statical stability of the air. Other values relative to variance are given, and the memoir is of a high scientific order.

RECENT FUNDAMENTAL WORK IN PHYSICS.—The address entitled "The Last Fifteen Years of Physics," which Prof. R. A. Millikan delivered at the annual meeting of the American Philosophical Society in April, is reproduced in Part 2 of the *Proceedings* of the Society for 1926. Sixteen of the twenty-one fundamental discoveries of the past thirty years fall within the last fifteen years, and there seems no sign of diminution of the rate of progress in the near future. Amongst the more recent discoveries may be mentioned that of isotopes by positive ray analysis, that of the excited atom, which Prof. Millikan thinks may be the foundation of a new era in science, the interpretation of the fine structure of spectral lines as due to changes in quantum numbers, the bridging of the gaps in the spectrum between electromagnetic and long heat waves and between ultra-violet light and X-rays, and the recent discovery that, by assuming every electron has unit angular momentum, we get an explanation of doublets to replace that previously provided—unsatisfactorily however—by an assumed change of mass of the electron with speed. His own discovery of cosmic rays of enormous power hitherto unknown—one of the most important and stimulating—gets an all too modest notice of nine lines.

ELECTRICAL CONDUCTIVITY OF CYANOGEN BROMIDE.—According to the theory of 'pseudo atoms' put forward by Grimm, it is possible to regard atoms possessing the same total nuclear charge as similar. If this idea is true, the cyanogen radical is like the sodium atom, and therefore its fused salts should conduct electrically. This reasoning led G. Glockler to study the electrical conductivity of fused cyanogen bromide (m p 52°). Details of the preliminary experiments and an approximate value for the specific conductivity are given in the *Proceedings of the United States National Academy of Science* for August 1926.

HYDRION CONCENTRATION AND PHOTOGRAPHIC EMULSIONS.—The effect on the sensitiveness of a gelatine emulsion of adding a little acid or alkali during its preparation has long been known in a general sense, and Messrs S O Rawling and J. W. Glassett, of the British Photographic Research Association, have sought to find more exactly the effect of changing hydrion concentration during the washing and digesting stages (*Journal of the Royal Photographic Society*. November 1926). The range of *p*H values studied extends from 5 to 9. They find that with samples of gelatine having widely different photographic properties, and emulsions precipitated in the presence or absence of ammonia, the photographic sensitiveness obtained after digestion is greater as the hydrion concentration is increased. With any one emulsion, on prolonged digestion, a steady value is obtained and maintained for a time which is different for each different *p*H value employed. The grain size and appearance seem to be unaffected, and in most cases, if digestion is continued long enough, the development velocities and shape of the characteristic curve of the emulsion also are independent of the hydrion concentration during digestion.

OXIDATION OF PHOSPHORUS VAPOUR.—In an examination of the oxidation of phosphorus vapour at low pressures, Chariton and Walta (*Zeit. fur Phys.*, p 547, October 1926) have found that, for a given vapour pressure of the phosphorus, there exists a definite critical pressure of oxygen below which no reaction takes place. They also found that this critical pressure was lowered by the addition of small quantities of argon, and at the same time the light emitted during the reaction was decreased in intensity. As a working hypothesis, the authors assume that the critical pressure of oxygen is that pressure above which each active centre is able to produce other active centres. Consequently, the argon atoms added may be considered to assist in the formation of active centres by means of 'collisions of the second kind,' and hence the reaction may proceed in the presence of less oxygen. It is found that when such centres are produced artificially, by electric discharge or by means of a glowing wire, the critical pressure of oxygen is lowered.

Atmospheric Electricity.[1]

THE director and staff of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington have of late years given much attention to atmospheric electricity, and have published several conclusions of much interest, the evidence for which is contained in the volume before us. Thus, although it includes a variety of other interesting matter—magnetic, meteorological, and instrumental—we shall confine our present remarks to the subject of the potential gradient of atmospheric electricity, a subject dealt with by Messrs Bauer, Ault, and Mauchly, especially the last mentioned.

Perhaps the most remarkable conclusion, due to Dr. Mauchly, is that re-stated on p. 402: "At least the greater part of the diurnal variation of the potential gradient over the oceans is due to a wave which progresses according to universal rather than local time. . . . All potential-gradient observations at sea tend to give values which are lower than the mean of the day if made in the forenoon of the Greenwich civil day, and values higher than the mean of the day if made in the afternoon of the Greenwich day."

The main evidence for this conclusion is a series of 24-hourly data from 59 Greenwich days, given on pp. 390-391. Details of the actual observations appear on pp. 212-265.

The natural way of checking Dr. Mauchly's conclusion would be to group the observations according to longitude. If we do so, taking 30° zones centering respectively at 0°, 30° E., etc., we find that there are only four zones—those centering at 180° E., 210° E., 240° E., and 270° E.—for which there are more than four days' observations. In an element so variable as potential gradient, uncertainties are sure to be large unless a considerable number of days is employed. Diurnal variations have thus been calculated only for the four zones stated, the 'days' available numbering respectively 9, 14, 9, and 10. Diurnal variations were also calculated for two groups each of five days from the 270° zone, and finally for the whole 42 days included in the four zones. Space allows us to mention only a few of the details, the hours referring to Greenwich civil time.

Zone.	Daily Mean.	Minimum.		Maximum.		Range.
E.	v/m.	h.	v/m.	h.	v/m.	v/m.
180°	128	2	112	20	152	40
210	106	3	93	19	136	43
240	124	6	100	15	156	56
270	133	0	113	19	165	52
270*a*	145	4	117	19	194	77
270*b*	122	23	101	12	160	59
42 days	121	3	105	19	148	43

The inequality derived from the 42 days accords with Dr. Mauchly's conclusion that potential gradient at sea tends to be below the mean in the Greenwich forenoon, and the times it gives for maximum and minimum, 19 h. and 3 h., are in general accord with his. But the 42 days results refer only to a limited part of the ocean, and the results from the different zones differ amongst themselves. In the case of the 270° zone the results from the two groups of days are widely different, and the inequality from the whole 10 days shows a prominent secondary maximum and minimum at 12 h. and 14 h. respectively.

When we look more closely into the data two unsatisfactory features appear. About 12 per cent. of the hourly values for the 59 days are interpolations; for the observations of 1921 the percentage is 21. In the majority of cases the interpolations represent arithmetic means from two observations separated by two hours, but in other cases they are of a more questionable character. For example, for 'day' 52 the earliest and latest observations available refer respectively to 18 h. on one Greenwich day and to 13 h. on the next. These appear as 13 h. and 18 h. on the same day, and data are interpolated for 14 h., 15 h., 16 h., and 17 h. as if this were the case. The probable existence of a progressive change in the 24 hours is neglected.

The second unsatisfactory feature is the total disregard of n.c. changes. Usually only 24 successive hourly values were obtained, and it is impossible to say what the n.c. change really was. So far as the run of the figures enables us to judge, it was usually very sensible, and sometimes very large. We have, for example, the following data assigned to three successive hours, 259 | 165, 184; 166 | 51, 53; 118, 139 | 266; 313, 300 | 150. In each case the entries which immediately precede and follow the vertical line represent respectively the latest and the earliest of the observations taken during the 'day.' If the hour at which the 'day' began was quite irregular, and if there were a very large number of days, uncertainties would naturally largely cancel out. But such cancellation cannot be assumed when the number of days is limited, and several of the inequalities, the results of which appear above, were apparently seriously prejudiced.

In the case of 210° E. longitude three n.c. discontinuities lead to an apparent excess of 160 *v/m* at 18 h. over 17 h., the excess in the aggregate from the whole 14 days being 182 *v/m*; and two n.c. discontinuities cause an apparent excess of 157 *v/m* at 19 h. over 18 h., the excess in the aggregate from the whole 14 days being only 92 *v/m*. Thus the maximum at 19 h. in the inequality from the 14 days may have been entirely due to the neglect of n.c. changes. As it so happens, these n.c. discontinuities in the case of the four zones considered were almost entirely confined to the (Greenwich) afternoon. Only one serious n.c. discontinuity appeared in the (Greenwich) forenoon. It led on 'day' No. 3 to an apparent fall of 98 *v/m* between 1 h. and 2 h., and was probably responsible for the hour at which the minimum occurred in the 180° zone. The effect of this discontinuity is not wholly negligible even in the case of the 42-day inequality. In spite of it, a remarkable feature stands out, namely, a close approach to constancy in the voltage from 1 h. to 6 h. G.M.T. Hourly means during the six hours vary only between 105·5 *v/m* at 3 h. and 108·7 *v/m* at 1 h. This suggests a diurnal variation, which is either very small or largely dependent on local time.

The results now obtained should not be regarded as disproving Dr. Mauchly's conclusions, but they unquestionably do suggest that further observations on somewhat different lines are required to justify any final conclusion. A term in the diurnal variation following universal time is not perhaps improbable *a priori*. The earth's surface varies notably in different zones, and there may be regions, *e.g.* the Himalayas, which exercise a dominant influence on the diurnal flow of the air-earth current on land. But even if a term depending on universal time exists, there may be even at sea terms of equal or greater importance depending on local time. The ideal arrangement to investigate the matter properly would be to have three similar ships—which need not be non-magnetic—with similar apparatus, observing simultaneously at three limited areas about the same latitude, the two extreme areas being about

---

[1] Researches of the Department of Terrestrial Magnetism, vol. 5: "Ocean Magnetic and Electric Observations, 1915–1921." Washington, D.C. Published by the Carnegie Institution of Washington, 1926. Pp. vii+430, with 15 plates and 31 figures in the text.

180° apart, and the third midway. Each ship should observe in succession at each area for a month or two, as continuously as possible. In any case, an overlap of two or three hours should be secured for each 'day's' observations.

The relation of potential gradient to sunspots has been dealt with by Dr. Bauer in various recent papers which have been discussed in NATURE. Dr. Mauchly refers on pp. 405-406 to the bearing of the ocean observations on this point. He says: "The mean values for each 3-month period . . . show throughout the years beginning with 1915, first an increase to 1916 or 1917, and then a gradual and consistent decrease to the end of 1921. This is so closely in accord with what has been observed at land stations, where reliable or undisturbed data of required extent are available, as to leave no doubt regarding the reality and universality of this phenomenon" (*l.c.* p. 405); and again: "in all latitudes for which there were sufficient observations . . . the mean values observed on cruise VI (mean epoch 1920·8) were from 15 to 20 per cent. lower than those observed in cruise IV. (mean epoch 1916·2)" (*l.c.* p. 406). These statements should, however, be taken in conjunction with the following two: "It should be noted that all potential gradient values shown in the graphs and tables of this report are of the order of 20 to 25 per cent. greater than those given in the author's earlier papers" (*l.c.* p. 397); and "At that time (1920), owing to various causes brought on by the War, there had been no final determinations of the instrumental constants to be used for reducing to absolute values the results of the . . . observations made aboard the vessel" (*l.c.* p. 387). Apparently all the observational data depend on reduction factors got out during expedition No. VI., and these are apparently assumed to have been unchanged since 1915. Those having experience in these matters may perhaps be pardoned a doubt whether the factors used in Dr. Mauchly's earlier papers were so much in error as he now supposes.

The general subject of sunspot influence is considered in more detail by Dr. Bauer himself, pp. 361-384. The following statement (*l.c.* p. 381) embodies his present opinions: "The general conclusion from the investigations, based on land and ocean results . . . is to indicate with a high degree of probability that during the cycle of 1913-1922 the atmospheric potential gradient increased with increasing sun-spottedness by at least 20 per cent. of its mean value for the cycle between the years of minimum and maximum sun-spottedness. The same statement applies with regard to measures of the diurnal variation and of the annual variation of the potential gradient." These conclusions are based on the results obtained by the *Carnegie* at sea and on the published data of the Ebro, Eskdalemuir, and Kew observatories. The methods employed seem practically the same as in Dr. Bauer's earlier papers on the subject. No notice seems to be taken of the criticisms which have appeared in NATURE, and no further vindication is supplied of the omission of the results from Potsdam, which gave a small decline in potential gradient with increased sun-spottedness. The reason assigned for disregarding Potsdam is alleged uncertainty as to the reduction factor. But uncertainty on this ground has been denied by the Potsdam authorities, and it seems scarcely likely *a priori* to have been more serious than in the case of the ocean observations which Dr. Bauer seems to have no doubts about.

As considerable use is made of the amplitudes and phase angles of Fourier coefficients by both Dr. Bauer and Dr. Mauchly, it may not be amiss to point out that the calculation of these coefficients from data in which large n.c. changes exist and have not been eliminated is unsatisfactory from the mathematical point of view. Unless the n.c. change is very small as compared with the daily range the effect of its neglect may be serious, especially in the case of the waves of least amplitude.

C. CHREE.

The Formation of Lactic Acid in Muscle.

A VERY important advance in our knowledge of this fundamental process has been made by Prof. Meyerhof in continuation of his well-known researches on the subject. Last January he announced (in *Die Naturwissenschaften*, 14, Heft 10) that he had succeeded in extracting the enzyme responsible for the production of lactic acid from carbohydrates in muscle, and gave an account of its properties. He has now carried matters a step further (*Die Naturwissenschaften*, 14, 32) and has been able to penetrate much more deeply into the mechanism of the change. The enzyme, obtained by extracting the finely divided muscle with isotonic potassium chloride solution at -1° to -2° and then centrifuging, readily forms lactic acid from starch and glycogen at a rate about two-thirds of that of the spontaneous formation of the acid in minced muscle. It is separated by ultra-filtration into a heat-labile inactive residue and a stable filtrate—the previously known coenzyme—which reactivates this residue. The coenzyme can be obtained either from muscle or yeast, and its addition greatly increases the amount of lactic acid producible from an excess of glycogen. The hexoses and the disaccharides are scarcely attacked, whereas lactic acid is freely formed, and at nearly the same rate, from glycogen, starch, and various degradation products of starch.

Hexosediphosphoric acid, the monophosphoric ester obtained from it by partial hydrolysis (Neuberg), and the isomeric monophosphoric ester from yeast juice (Harden and Robison) are all attacked. This decomposition of hexosephosphoric acid into equivalent amounts of lactic acid and phosphoric acid is, however, independent of the presence of the coenzyme which is necessary for the decomposition of glycogen and starch.

The production of lactic acid, either from glycogen or glucose, is preceded by the formation of a hexosephosphoric acid, and the reason why glycogen is the more easily acted on appears to be that a reactive hexose is formed from it which is more readily esterified than glucose in its stable form.

Meyerhof, hoping to be able to accelerate the action on the hexoses, turned to yeast—that unfailing storehouse of physiological surprises—and met with astonishing success. By precipitating autolysed yeast with 50 per cent. alcohol he obtained a new activator—different from zymase, coenzyme, and insulin—which, when added to the mixture of muscle enzyme and the hexoses, increases the rate of lactic acid formation until it amounts to several times that of its production from glycogen and 10 times that of the spontaneous production of lactic acid in minced muscle. The decomposition of glycogen, on the other hand, is scarcely affected.

At the same time the esterification of the phosphoric acid is still more accelerated, and the result is that during the first 15-30 minutes there is a rapid accumulation of hexosephosphoric acid, which continues so long as both hexose and free phosphoric acid are present. The rate of production of the acid then falls rapidly, and is followed, when the supply of both hexose and phosphoric acid is exhausted, by a stage in which a slow production of lactic acid and phosphoric acid in equivalent amounts takes place. The hexosephosphoric acid formed is approximately equivalent in amount to the amount of lactic acid produced.

This state of affairs presents, as will be seen, the most complete analogy to what occurs in alcoholic fermentation, with the difference that in one case the product is lactic acid and in the other alcohol and carbon dioxide. There is the same great acceleration in the rate of the reaction, accompanied by the accumulation of hexosephosphoric acid, the same drop in the rate when the free phosphoric acid is exhausted, and the same succeeding slow rate of change. As in the case of alcoholic fermentation, fructose reacts much more rapidly than glucose. There seems to be no doubt that the same fundamental change is in progress in the two cases.

Meyerhof believes that the hexosephosphoric acid produced is converted whilst *in statu nascendi* into the final products—lactic acid or alcohol and carbon dioxide (or some precursor of these) and phosphoric acid.

As, however, the rate of esterification is greater than that of decomposition, some of the phosphoric ester becomes stabilised in the less reactive form in which it can be isolated.

In the intact yeast cell and the natural muscle there is no accumulation of hexosephosphoric acid, "probably because, as the result of an accurate co-ordination, the whole of the labile ester produced is fermented, and not only about one-half of it, as in the extracts."

This explanation scarcely accounts for the approximate equivalence between the amounts of hexose decomposed and converted into the stable ester, and there is doubtless more yet to be learned on this point.

The striking similarity established by Meyerhof between the changes of carbohydrates in muscle and in the yeast cell is seen to be much closer than has been believed. The remarkable phenomena accompanying alcoholic fermentation are now duplicated in the case of lactic acid production, and it may reasonably be expected that most of the fermentative decompositions of the sugars will be found to be initiated in a similar manner.

It is a great achievement to have pushed the analysis of the production of lactic acid so far, and further results of this line of investigation will be awaited with the greatest interest.

ARTHUR HARDEN.

A Royal Collection of Scientific Instruments.

AN interesting historical document is described by Mr. Robert S. Whipple in "An Old Catalogue and what it tells us of the Scientific Instruments and Curios collected by Queen Charlotte and King George III." (Reprinted from the *Proceedings of the Optical Convention, 1926*. Part 2.) The catalogue, which has been preserved at the Kew Observatory, was prepared in 1770 or a few years later. A reproduction of the first page of the catalogue is given, the complete catalogue (319 entries), and a "Catalogue of Presents by Sundry Persons" (77 entries) being printed as an appendix to the paper.

Whilst the first catalogue is confined wholly to scientific apparatus and instruments, a large proportion being of the educational or teaching type, the 'presents' are mainly of the 'natural history' type, including such objects as 'a dried cat,' 'a lizzard in spirits,' 'fosils from Virginia,' 'two Batavia rats,' 'two spiders from Bardadoes,' etc. In the latter list the names of the distinguished donors are given.

Before describing the contents of the collection, Mr. Whipple gives an account of the foundation of the King's Observatory at Kew for the purpose of observing the transit of Venus in 1769. Some of the instruments included in the catalogue were used in the observations, and the original notes (preserved in the Library of King's College, London) by Dr. Demainbray recording the observations are published, it is believed for the first time. King George III. acted as an assistant during the observations. Queen Charlotte and the Princes Ernest and George of Mecklenburg-Strelitz were present, and others taking part were Col. Desaguliers, Rev. Geo. Wollaston, Stephen Rigaud, Justin and Benjamin Vulliamy, Jeremiah Sisson, and John Cuff.

Full details are given of the instruments used and of the observations made. It is interesting to read that "His Majesty the King who made his Observation with a Short's Reflecting Telescope, magnifying Diameters 170 Times, was the first who saw the Penumbra of Venus touching the Edge of the Sun's Disk." There is a note afterwards to the effect that "his Majesty thinks he saw it before he gave his Signal to Doctor Demainbray, who attended at the Regulator. And that Mr. Sisson (fearful of giving a false Alarum) waited an Instant before he caused Mr. Cuff to ring the Bell."

The collection of instruments and apparatus as specified in the Queen's Catalogue, with other objects afterwards acquired, remained as a national collection in the Kew Observatory until 1841, when the Government decided to discontinue the maintenance of the Observatory. Mr. Whipple gives in detail the circumstances leading to this decision, and the consequent distribution of the collection to various institutions and individuals.

Some of the instruments and apparatus which went to King's College, with a request that "they should be preserved together as a whole" (forming the George III. Museum), are described and illustrated. The present locations of some of these, as well as of instruments which went to other institutions, are given.

Of the larger instruments included in the Catalogue, perhaps the best known to the general public are the large eight-feet mural quadrant by Jeremiah Sisson, and the observatory clock by Benjamin Vulliamy. These have been exhibited for many years in the Science Museum at South Kensington. Of the transit instrument, which went to Armagh Observatory, only the object-glass and the mahogany stand for lifting and reversing the telescope are still in existence, the object-glass being used at present for testing planes. The lens and some parts of the five-feet "astronomical sector in dome," as well as the six-inch telescope (probably that used by the King in 1769) made by Short in 1745, are still preserved at Armagh.

Mr. Whipple gives interesting evidence of the circumstances in which the valuable old microscopes were acquired by the late Sir Frank Crisp from the George III. Museum. The King's College authorities, though aware of the great historical value of the instruments, agreed to the transference only after much pressure, and "having been given the assurance that the Crisp collection was destined for the nation." Mr. Whipple adds: "The fact that the assurance was not fulfilled illustrates the importance of entrusting instruments or other objects of historical interest to a National Museum."

Since this interesting and valuable paper was read at the Optical Convention last April, the George III. collection, which was then still at King's College, has been transferred on loan to the Science Museum.

D. B.

University and Educational Intelligence.

CAMBRIDGE.—A valuable bequest of works of art, including a collection of the finest Italian majolica, has been left to the Fitzwilliam museum along with 10,000*l*., as an endowment for the purchase of works of art, by the late Right Hon. F. Leverton Harris, of Gonville and Caius College.

Dr R. R. Marett has been appointed to the Frazer lectureship in anthropology.

It is proposed to abandon the examinations for the diploma in horticultural science, it having proved impracticable to acquire adequate facilities for the teaching.

Mr. E G. D. Murray has been elected to a research fellowship at Christ's College.

SYDNEY.—The following appointments are announced: Mr. John Anderson (Edinburgh) to be professor of philosophy in succession to the late Prof. B. Muscio; Dr. W. S Dawson, of the Maudsley L.C C. Hospital, Denmark Hill, London, to be professor of psychiatry in succession to Sir John Macpherson; Mr. H. Finnemore (Guy's Hospital Medical School), to be lecturer in pharmacy in succession to Mr. S. H. Stroud; Dr T. Iredale, of Armstrong College, Newcastle-on-Tyne, to be lecturer in chemistry, in succession to Prof J. A. Schofield.

THE University College of North Wales, Bangor, announces in its Calendar for 1926-27 the opening of new War Memorial Laboratories for all the science departments, excepting applied electricity. This development was rendered possible by the help of the Council of the North Wales Heroes' Memorial Fund, the total subscriptions to which, including an initial gift in 1917 of 20,000*l*. by Sir R. J. Thomas, amount to nearly 100,000*l*. The interesting historical summary given in the preface to the Calendar recalls the remarkable unanimity with which all classes of the community contributed to the establishment of the College forty years ago. Never before, it says, in so short a period, have so many persons, either in England or in Wales, subscribed towards a movement for the promotion of higher education. In the first twelve months more than 30,000*l* was subscribed by nearly 8000 donors. The total sum subscribed towards the College since its establishment is 407,735*l*. One of the two main types of approved schemes of study for the B.A. (pass) degree is known as the scheme of civic studies, the general aim of which is to emphasise the more definitely humanistic side of the subjects in the arts curriculum and cultivate a more intelligent appreciation of national life.

THE directors of the Commonwealth Fund of New York City, which was founded in 1918, awarded in 1925 and 1926 a number of Commonwealth Fund Fellowships to British graduates for study in selected American universities. Entries last year numbered 178, and the committee of award states that the general level of attainment was higher than that of 1925. A maximum of twenty fellowships are awarded each year, and candidates must be of British birth who are domiciled in Great Britain or Ireland, and less than thirty years of age. Personality, health, and character are taken into account as well as intellectual ability. With the exception of purely clinical work in medicine, which is not considered likely to be promoted by the type of travelling fellowship offered, there is no limitation as to subject of study. In 1927, for the first time, the committee of award will be empowered to appoint three "Extra Fellowships," which are intended for candidates from British Dominions who have studied in British universities or such as hold appointments in Colonial administrative or educational service. The annual value of a Commonwealth Fund fellowship is about 600*l*. Further information can be obtained from the secretary of the Committee, Commonwealth Fund Fellowships, 50 Russell Square, London, W.C.1.; applications on the prescribed forms must be completed and reach him by February 19.

THE report of Battersea Polytechnic for 1925–26, though registering a slight increase in comparison with the preceding year's record of work done, directs attention to the fact that its valuable plant would be more fully utilised but for the raising of the fees against residents of Surrey (Wimbledon and Croydon), owing to which the technical college has suffered a continuous decline in the number of its day students since 1920–21. Judged by the list of academic honours gained in 1925–26, the Polytechnic has achieved very considerable success in the field of higher education in science. It includes three doctorates, three degrees of M.Sc., and twenty-five B.Sc. In the Chemistry Department a substantial amount of original research work was done, and led to the three doctorates and to the Meldola medal awarded by the Institute of Chemistry. Among the subjects in which there are specialist courses in this Department are paper testing and making, chemical engineering, soaps and detergents, mineral oils and waxes, catalytic hydrogenation and secondary constituents of plants. The Department of Hygiene and Public Health, which trains candidates for such posts as health visitor and sanitary inspector, has expanded largely in the past three years, as has likewise the Training College of Domestic Science, now the largest of its kind in Great Britain, which sends out teachers and organisers to all parts of the Empire and to foreign countries. For some time past all day students, in whatever department of the Polytechnic, who have satisfactorily completed the full course, have obtained employment.

"UNIVERSITY extension" in the United States includes (1) instruction in agriculture and home economics provided with the aid of Federal subsidies through the land-grant colleges, and (2) very varied activities of universities and colleges in other fields to which the name "General University Extension" has been applied. A report on this latter group of activities by the Dean of Extension of the University of Texas has been published by the Bureau of Education as Bulletin, 1926, No. 5. The progress of extension of leading universities impels the writer of the report to the conclusion that "before many decades have passed all Americans, both old and young, will have the advantages of university training and university service at their very doors." President Birge, of the University of Wisconsin, the pioneer in America in extension work, holds that it is essential not only for individual progress on the part of students, but equally "as a means of preventing the crystallisation of social groups." Among the extension activities which have shown exceptional development in the past two years are radio courses. It has been proved that courses of instruction in foreign languages, social sciences, etc, can easily be given by this method, which combines the lecture with written reports. One university enrolled 1636 radio-course students belonging to more than half the States and to Canada, the enrolment fee being one dollar, and entitling the student to receive mimeographed study material. Some of the other branches of extension work are described as community drama, home-reading courses, graduate medical lectures, labour education, community institutes. The total number of students enrolled in extension and correspondence courses in 1923–24 was 141,000.

Contemporary Birthdays.

December 17, 1853. M. Émile Roux, For.Mem.R.S.
December 17, 1861. Mr. Edward Heron-Allen, F.R.S.
December 18, 1856. Sir J. J. Thomson, O.M., F.R.S.
December 19, 1852. Prof. A. A. Michelson, For.Mem.R.S.
December 20, 1876. Dr. Walter Sydney Adams.
December 22, 1862. Dr. Vaughan Cornish.

DIRECTOR of the Pasteur Institute, Paris, a foreign member of the Royal Society of London, and Copley medallist, Dr. Émile Roux was born at Confolens. Early in his career he worked in Pasteur's laboratory, and in the course of time became his collaborator in pathological research. In 1889 Roux delivered, on behalf of M. Pasteur, whose health did not allow attendance, the Royal Society's Croonian lecture, on the subject "Les Inoculations Préventives."

Mr. E. HERON-ALLEN is a Londoner, and was educated at Harrow. He has written many papers on the Foraminifera, including one published in the *Philosophical Transactions* (1915), entitled "Bionomics of the Foraminifera." In 1916–18 Mr. Heron-Allen was president of the Royal Microscopical Society. He has done original work in many departments of natural history, and is, in addition, an authority on Persian literature.

Prof. MICHELSON was born at Strelno, Germany. Entering and graduating at the U.S. Naval Academy, he joined the Nautical Almanac Office, Washington; afterwards he studied at the Universities of Berlin, Heidelberg, and the École Polytechnique, Paris. From 1889 until 1892 he was professor of physics at Clark University, Worcester, Massachusetts, leaving to become professor and head of the Department of Physics in the University of Chicago. A foreign member of the Royal Society of London, he was awarded the Copley medal in 1907. In that year he was also Nobel laureate in physics. Prof. Michelson was a pioneer in the construction of interferometers, and his optical inventions have rendered possible the reproduction of accurate metric standards, which are now widely used. He has received many foreign recognitions; he is Hon. Sc.D., Cambridge, and an associate of the Royal Astronomical Society, which awarded him its gold medal in 1923. Prof. Michelson was added to our roll of "Scientific Worthies" in NATURE of January 2, 1926.

Dr. W. S. ADAMS was born at Antioch. He was sent to Dartmouth College, Hanover, U.S.A., and afterwards to the University of Chicago. Appointed an assistant at Yerkes Observatory, he removed in 1901 to fill a similar post at Mount Wilson Observatory, California, becoming Director in 1923. A member of the National Academy of Sciences, Washington, he is one of its Draper medallists. The Royal Astronomical Society awarded Dr. Adams its gold medal in 1917 for his investigations in stellar spectroscopy. Last year his observations on the spectrum of the companion of Sirius enabled him to confirm Einstein's prediction of the gravitational displacement of spectral lines, and also Eddington's calculations of the very high density of white dwarf stars.

Dr. VAUGHAN CORNISH, a zealous geographer, was born at Debenham, Suffolk. He was educated at St. Paul's School and the Victoria University, Manchester. In 1900 the Royal Geographical Society allotted him the Gill Memorial Award for extended researches on sea-beaches, sand-dunes, and wave-form in water. President of Section E (Geography) at the Liverpool meeting of the British Association in 1923, he gave an address on the British Empire regarded as a maritime organisation. He is the author of "The Great Capitals: an Historical Geography" (1923).

Societies and Academies.

LONDON.

Optical Society, November 11.—J. W. T. **Walsh** and W. **Barnett**: The effect of slightly selective absorption in the paint used for photometric integrators. A sensibly non-selective internal coating for photometric integrators is very difficult to produce and still more difficult to maintain. When lamps of different colour temperatures are compared in an integrator with an internal coating which shows selective absorption in, say, the blue, the values of candle-power obtained for the lamps of lower colour temperature will be too high, and vice versa. A simple method is given for calculating the magnitude of the effect for sources having a spectrum approximating to that of a black body. In work on normal type electric lamps, to an accuracy of 1 to 2 per cent., a quite noticeable coloration of the light may be produced by the sphere (either on account of paint or window selectivity or both) without the necessity for making any correction to the measured values of candle-power.—Conrad **Beck**: An accurate method of ascertaining the position of the focal point of an optical system. The method consists essentially in placing a diaphragm with two slit apertures behind the object-glass to be tested, the directions of the slits being at right angles to one another, and finding the position where the images form a symmetrical cross. Results of measurements by this method of the zonal aberrations of apochromatic microscope object-glasses are given.

PARIS.

Academy of Sciences, November 15.—Georges **Perrier**: The regular triangulation of Morocco. Outline of geodesic work done in Morocco since 1910, with key map.—F. E. **Fournier**: Effects useful or detrimental to the velocity of ships.—Charles **Moureu**, Charles **Dufraisse**, and Marius **Badoche**: Autoxidation and antioxygen action (XX.). Catalytic actions of a new series of nitrogen compounds. General observations on the nitrogen compounds. Details of the study of the catalytic properties of thirty-seven new nitrogen compounds.—H. **Douvillé**: The marbles of Sarrancolin and of Saint-Béat in the Central Pyrenees.—Jean Baptiste **Senderens** and Jean **Aboulenc**: The etherification of the hydroaromatic alcohols. Cyclohexanol, heated with 2 per cent. sulphuric acid (concentrated or diluted) does not give cyclohexyl oxide, but a mixture of cyclohexene and its polymer. Similarly, a mixture of cyclohexanol and a fatty alcohol fails to give a mixed ether. On the other hand, the hydroaromatic alcohol and an aromatic alcohol under the same conditions gives a mixture containing benzyl ether and the mixed ether.—Camille **Sauvageau**: The development of *Colpomenia sinuosa*.—A. **Calmette**, J. **Valtis**, and M. **Lacomme**: The intra-uterine transmission of the tubercle virus from mother to infant. In the course of some grave tuberculous infections, the passage of the tubercle virus from mother to fœtus during gestation is less exceptional than has hitherto been supposed.—Bertrand **Gambier**: The deformation of surfaces and the method of Weingarten.—E. **Goursat**: Observations on the preceding communication.—**Potron**: The fundamental theorems of the theory of finite continuous groups of transformations.—R. **Wavre** and A. **Bruttin**: A continuous transformation and the existence of an invariant point.—J. **Delsarte**: Rotations in functional space.—E. F. **Collingwood**: A theorem on integral functions.—S. **Saks**: The differentiation of the area of surfaces.—G. **Vranceanu**:

Non-holonomial spaces.—Jean **Chazy**: The field of gravitation in the interior of a hollow sphere in rotation in the relativity theory.—H. **Beghin** and P. **Monfraix**: The realisation of a damped zenithal gyrostatic compass.—R. **Swyngedauw**: The slipping of belts.—J. F. **Saffy**: The influence of prolonged maintenance, at a red heat, on the resilience of some metals used for exhaust valves. Measurements of resilience of four samples of chrome-steel of different composition are given. These steels had been submitted to a temperature of 600° (in one case to 850°) for varying periods (maximum twelve weeks), before taking the measurements. An austentitic chrome-nickel steel retained a practically constant resilience, even after twelve weeks and at 850° C. This steel is markedly superior to other steels for use in valves of internal combustion engines.—R. **Mazet**: The formation of liquid jets.—Robert **Lévi**: The theory of universal and discontinuous action.—**Sauger**: Energy extensions of the Newtonian potential.—A. **Guillet**: The value of the constant of time most favourable to the direct electrical maintenance of an oscillatory movement.—L. **Caignard**: The variation of the dielectric constant of benzene with pressure. The high frequency oscillations used in the measurements had a wave-length of 6425 metres, the electric field applied to the dielectric 650 volts per cm., maximum pressure, 22 atmospheres. At constant temperature the dielectric constant is a linear function of the pressure.—G. **Gamow**: L. de Broglie's theory of waves of phases.—C. **Mihul**: The structure of the spectrum of oxygen of the second order.—D. K. **Yovanovitch** and Al. **Proca**: The slow β-rays of mesothorium-2.—Maurice **Lecat**: Azeotropism, particularly of binary systems with closely chemically related constituents. An attempt to measure the tendency of two substances to form a mixture of constant boiling point, with special reference to the chemical nature of the two constituents. Numerical data are given for twenty-eight binary mixtures forming constant boiling mixtures.—F. M. **Ostroga**: Chrome-cobalt steels. From the point of view of the influence of the temperature of heating and velocity of cooling on the constitution of these alloys, the chrome-cobalt steels show a sensibility at least equal, if not superior, to that of chrome-nickel high-speed steels.—J. **Cournot** and R. **Pages**: Studies of the viscosity of copper and its alloys.—E. **Tassilly** and R. **Savoire**: The spectrophotometric determination of nitrites and nitrates by diphenylamine sulphate. With the instrument used (Ch. Féry spectrophotometer) the useful range is from 0·1 to 5 milligrams of N_2O_5, with a possible error of 0·1 mgm.—J. A. **Le Bel**: The stereochemistry of the ethylene derivatives. The experimental results in a recent note by Dufraisse and Gillet afford a confirmation of the theoretical views of the author.—**Lespieau** and **Deluchat**: 1,7-Octadiine. This hydrocarbon, $HC:C-(CH_2)_4-C:CH$, has been isolated, starting with dibromobutene, and its compound with silver nitrate prepared.—E. **Raguin**: The presence, to the north-east of Vanoise, of schists assimilable to those of the Tertiary Flysch.—Octave **Mengel**: An apparent analogy between the Alpino-Dinaric and Pyreneo-Iberic border. Common origin of the Alpine lakes and ancient Pyrenean lakes.—L. **Picard**: The Cenomanian of Carmel (south-east of Haifa).—Henri **Coupin**: The rôle of fleshy pericarps.—E. **Chemin**: A new species of Colaconema on *Asparagopsis lamifera*.—René **Souèges**: The embryogeny of the Papaveraceæ. The development of the proembryo in *Papaver Rhœas*.—E. **Chemin** and R. **Legendre**: Observations on the existence of free iodine in *Falkenbergia Doubletii*. Free iodine has been found by M. Sauvageau in *F. Doubletii* collected at Guéthary and at Cherbourg. The authors have examined specimens from Brest and from Glénans, but no free iodine could be detected. Weak acids, even carbonic acid, set free iodine, which hence would appear to be present as a labile compound other than iodide. O. **Munerati**: Observations on the seed yield of beetroot in the first year.—Lucien **Daniel**: Intermittent heredity in the Jerusalem artichoke.—Adrien Davy de **Virville**: The influence of submersion on the mode of development of a moss: *Aulacomnium androgynum*.—J. **Dubar** and G **Thieulin**: An attempt at the determination of the static refraction of the eye of the dog and cat.—Mme. Marguerite **Lwoff**: A mode of asexual reproduction in a Hydra of the family of the Tubularidæ.—Louis **Roule**: The displacements of *Orcynus thynnus* (or *Thunnus thynnus*) in the western basin of the Mediterranean.—L. **Lutz**: The soluble ferments secreted by the Hymenomycetes fungi: simple antioxygen actions.—V. **Omeliansky** and Mlle. M. **Kononoff**: A method of culture of the bacillus causing the retting of flax.—N. **Bezssonoff**: The true specific régime of experimental scurvy. Heated milk contains an appreciable proportion of vitamin C, and this is the cause of its varying effects on guinea-pigs. An alternative diet is suggested which gives more definite results.—L. **Ambard** and F. **Schmid**: The treatment of respiratory syncope by inhaling carbon dioxide. An arrest of respiration in a dog produced by a dose of chloralose, on which artificial respiration was without effect, was immediately removed by causing the animal to inhale a mixture of air and carbon dioxide. It is suggested that in many cases this method possesses advantages over artificial respiration.

VIENNA.

Academy of Sciences, October 21.—A. **Kailan**: The chemical effects of the penetrating radium radiation. The rays from 110 milligrams of a radium preparation were passed through 1 mm. of glass and allowed to act for more than 1000 hours on uric acid, on pyridin, on anilin, on nitrobenzol. Slight changes were noticed.—F. **Holzl**: Organic acids and bases in non-aqueous solution. Conductivity measurements were made.—S. I. **Mayr**: Free albumin crystals in the endosperm of the seeds of *Loranthus europaeus*.—R. **Weiss** and W. **Knapp**: Triphenylmethanes the benzene rings of which are interconnected.—S. **Loewe** and E **Spohr**: Detection and determination of contents of the female oestral hormone in the female organs of the vegetable kingdom. Experiments were made on mice and rats with extracts prepared from the flowers of the yellow water-lily and from willow catkins.—P. **Ludwig**: Tensile strength, cohesion, and danger of fracture. The fundamental factor in brittleness depends on the ratio of rigidity of form to tensile strength.—R. **Rotter**: The condensation of unsaturated compounds with diazomethane. Condensation of diazomethane with carbon disulphide and xyloquinone.—R. **Seka** and H. **Sedlatschek**: Complex compounds of pyromellithic acid anhydride.—G. **Klein**: Assimilation of nitrates by moulds.—N. A. **Puschin** and B. **Vaic**: Equilibrium in binary systems which contain guaiacol as one of the constituents.

October 28.—F. **Heritsch**: The tectonic 'window' [a break in a sheet-fold or overthrust layer, through which lower rocks are exposed] at Felsbach.—R. **Seka** and K. **Sekora**: Reduction products of dinaphtanthracene-diquinone.

Taxonomy in Biology.

WHEN Peter Camper, the great Dutch anatomist, was proposed for election as a foreign member of the Linnean Society of London in 1788, he wrote refusing in very emphatic terms to be associated with a society which bore the name of the founder of modern systematic biology. The incident is typical of an attitude towards the systematist on the part of those cultivating some of the other branches of biology which did not begin with Linnæus, and has by no means ended to-day. There is, however, one branch of biological research the dependence of which on the work of the systematist cannot be overlooked. The economic biologist, at any rate, must begin by finding out the names of the species of animals or plants with which he is dealing. Without their names he cannot profit by the experience of the past, nor can he transmit his results for the benefit of the future.

It is not surprising, therefore, to find that in a recent discussion before the Association of Economic Biologists on "The Place of the Systematist in Applied Biological Work,"[1] all the speakers emphasised the fundamental importance of systematics. Dr. James Waterston, in opening the discussion, gave a description of the work of the systematist which deserves to be thought over. "He finds in nature communities or groups of similar individual organisms which he calls species, and he makes it his business to arrange these and to summarise the salient facts about them in the simplest and most intelligible form." While the basis of his arrangement must be morphological, neglecting neither external form nor internal anatomy, he may also get help from other fields of work and take account of the results of the geneticist or the physiologist.

This is excellent if not quite exhaustive, but some of the later speakers in the discussion seemed to imply that the only help the economic biologist could get from the systematist was an answer to the question 'What is the name of this?' This estimate of the value of the systematist's work is widely held if it is not often frankly expressed. A distinguished biologist once told the present writer that the search for a natural classification was no part of a systematist's business. His job was identification, not classification, and he had only to devise some kind of key or card index which would enable the organisms to be quickly and easily sorted into species. If he cared he might amuse his leisure by speculating on the affinities of these species, but, so far as the really scientific branches of biology were concerned, an artificial classification was as good as, and might even be better than, any other.

---

[1] *Annals of Applied Biology*, vol. 13, No. 3, August 1926.

The idea underlying the view thus drastically expressed would seem to be that since the categories of the physiologist, the ecologist, the geneticist, and so on, often cut across the divisions of the most natural (that is, phylogenetic) classification we can devise, taxonomy is without interest or importance for workers in these other fields. It would not be difficult to show that this conclusion is far from being justified for any branch of biology. For the present, however, it is enough to point out that the economic biologist, although identification is his primary need, cannot afford to neglect the help that he may get from the improvement of classification.

In the course of the discussion mentioned above, Mr. J. C. F. Fryer pointed out that "the ability to place an organism in its correct group would often yield invaluable clues as to its biology and the part it might be playing in the problem in hand." In other words, the chances are that an organism will approach, in its habits and reactions, those that come nearest to it in morphological characters. A parrot may have the feeding habits of a hawk and a kingfisher may live in a waterless country and feed on lizards, but these exceptions must not obscure the fact that in defining the systematic groups of parrots or of kingfishers we are also defining, although somewhat less strictly, bionomic groups. A crab may live on land or have a direct development, but as a rule an animal with the morphological characters of the Brachyura may be expected to have aquatic habits and to hatch as a zoea larva. On merely practical grounds, therefore, the card index idea of biological systematics is inadequate.

On the other hand, the systematist, if he is to deserve the consideration of his scientific colleagues, must not allow himself to become immersed exclusively in the minor problems of specific distinction, although these may often be as fascinating as any crossword puzzle. The natural system of classification may seem, for some groups of organisms, to defy discovery, but each step towards it holds the promise of added usefulness in possibly remote fields of research.

We may close, as we began, with a story, but it is to be hoped that this one is apocryphal. Once upon a time, it is said, a young zoologist wrote a paper, which he sent to the Royal Society. The title of the paper ran somewhat thus, "On the development of a certain system of organs and its bearing on the classification of the group of animals in which it occurs." In due course the author received notice that the paper had been reported on favourably and would be accepted for publication provided that he removed from the title the reference to classification!

W. T. C.

Biological Synthesis: Hopes and Obstacles.

The Physiology of the Continuity of Life. By Prof. D. Noël Paton. Pp. x+226. (London: Macmillan and Co., Ltd., 1926.) 12*s*. net.

THERE never was a greater opportunity for successful and fruitful synthesis in science than exists now in respect of general biology. At last we know the main outlines of the laws of most vital phenomena—comparative morphology, physiology, embryology, *Entwicklungsmechanik*, cytology, heredity, evolution, ecology. Never in the past has there existed the possibility which exists to-day—the possibility of erecting a unified science of biology, in the same sense in which there has existed for some time a unified science of physics, in which each advance in each separate branch means an advance in the whole, and not merely another step down an isolated track.

When I saw the title of Prof. Noël Paton's book I hoped that he would give us a valuable synthesis in that broad field of biology concerned with reproduction. But I must at the outset confess that those hopes are far from being realised. Indeed, the book is in many ways a step in the wrong direction. In other fields than the author's special one, notably in regard to heredity, it attempts to destroy those principles which have already been established, and betrays an unfortunate lack of acquaintance with the essentials of many of the problems involved. On the other hand, within his own special field, and notably in dealing with the interrelations of the endocrine organs and their effects on reproduction, we feel all the time that general principles are lurking in the background, but that for some reason the author has not made them evident.

The major part of the book is 'biological,' in the current sense, as against physiological *sensu restricto*, and discusses types of reproduction, inheritance, sex and its determination, the theory of the germ-plasm, and the inheritance of acquired characters. The most noteworthy feature of this section is the author's determined attack upon neo-Mendelism, including the whole factorial idea and the chromosome theory. Prof. Paton dismisses all such with the blessed word 'static,' and seeks to substitute more 'dynamic' conceptions, in terms of what he calls *hereditary inertia* and *definite lines of metabolism*. His main attack, however, rests upon an elementary, but very fundamental, misapprehension.

The simplest way for me to substantiate this statement will be to begin with a brief outline of the position to which Mendel, Bateson, Morgan, and Goldschmidt, to mention only the four outstanding names, have brought the factorial theory of heredity. It is as follows. The hereditary constitution of at least all higher organisms consists of a number of units (factors or genes), each of which may exist in a number of forms (allelomorphs); these genes exist in definite proportions, and are arranged in a definite order; the whole gene-complex is divided up among the separate chromosomes, which in Drosophila have been shown to correspond to the linkage-groups established by genetic experiments. The mode of action of a particular factor is not something absolute or unalterable. It depends (*a*) upon the totality of other factors with which it is associated (theory of chromosomal and genic balance—which is not even referred to by Paton); and (*b*) upon the environmental conditions. The analogy between, on one hand, the hereditary constitution and its component factors, and on the other, an organic molecule and its component atoms, is complete, except that we have not yet been able to obtain single factors in isolation.

It should be noted that Mendel's and Morgan's theories concern almost exclusively the *distributive* mechanism of heredity, whereby new hereditary combinations arise; Morgan himself laments our comparative ignorance as to the methods by which factors come to exert their influence during ontogeny.

On this last point, however, others have brought forward evidence to show that some factors at least are concerned with qualitative differences in metabolism (*e.g.* factor for yellow colour in mice causing, in addition, adiposity in single dose, death *in utero* in double dose; factor for wrinkled condition of peas causing a different condition of the reserve carbohydrates); or with quantitative differences in rate of some definite metabolic process (Goldschmidt's multiple series of sex-factors in Lymantria; Ford's factors affecting rate of melanin-production in Gammarus).

Now Prof. Paton makes the extraordinary error of assuming that to adopt the Mendelian idea is to suppose that the effect of a factor (or of a chromosome, as in sex-determination) is always identical. After this, it is naturally simple for him to demolish the Mendelians —only, unfortunately, it is not the Mendelians he is demolishing, but imaginary beings of his own creation. Every standard text-book of genetics (I have verified it for those of Morgan, Goldschmidt, Baur, Babcock, and Clausen, and Crew) makes a special point of explaining that the fundamental assumption of Mendelism is the constancy of *factors*; while the *characters* affected by factors naturally *cannot* be constant, since they are always the product of the hereditary constitution interacting with a varying environment.

Prof Paton (p. 103) states that "if chromosomes are the determining factor [as regards sex] the characters should be clear-cut and distinct," and there should never be intersexuality: p. 100, "on the chromosome theory of sex-determination the lability of sex is most difficult to understand": p. 45, "There is good evidence to show that factors other than the chromosomes act in determining the line of development." (This last truism, accepted by every geneticist, is aimed at the factorial hypothesis!)

Prof. Paton's misunderstandings may perhaps best be illustrated with reference to linkage. He speaks of linkage as a 'hypothesis.' This it is not; it is a name invented to cover the *fact*, which any one can verify, that certain characters and factors stay together more often than they segregate.

Again (p. 107): "Suppositions as to crossing-over as well as 'cross-exchange' itself have in themselves something quite improbable. Especially remarkable are the facts that their exchange is said to take place only in one sex . . ." (*a*) It is of course quite inaccurate to state that crossing-over always occurs only in one sex, but this is Prof. Paton's error, not Morgan's. (*b*) The exchange not only is *said* to occur in only one sex of Drosophila but actually *does* do so, as Prof. Paton could verify for himself if he would take the trouble. Finally, suppositions as to crossing-over may be "quite improbable," but crossing-over itself is again merely a convenient name for a set of *facts*, namely, the existence of linkages that are not complete.

On p. 34 Prof. Paton italicises part of a statement by Morgan, namely: "the percentage of cross-overs is definite *for a given stock of a given age and under given environmental conditions*," and proceeds to treat this as a damaging admission. To this, and to his whole view that if neo-Mendelism is correct, then sex and every other factor-dependent character must be fixed and unalterable, I would like to oppose myself most vigorously. It is a denial of the ordinary canons of experiment, and, indeed, of common sense. Because the same dose of thyroid produces tadpoles' metamorphosis at high temperature but not at low temperature, is thyroxin therefore not a definite chemical individual? Or again, does Prof. Paton expect the same physiological preparation always to give the same result, even if the salt composition or the *p*H of the perfusion fluid be altered? Chromosomes being living constituents of the cell, how is constancy of crossing-over to be expected if the environment alters?

When we come to details, matters are not much better. On p. 34 we are told that in the cross between normal and bar-eyed Drosophila, "The F2 shows all gradations from bar-eye to normal eye." This surprised me so much that I have looked up the original papers (Tice, *Biol. Bull.* 26, 1914; Morgan and Bridges, *Carneg. Inst. Publ.* 237, 1916). The statement is simply incorrect. In fact, *bar* segregates so well that it is used as a fixed locus in linkage determinations. The assertion should at once be withdrawn. P. 30, and elsewhere, Prof. Paton adduces against Mendelian ideas the fact that dominance is not always complete. As was early recognised, however, dominance is a sporadic phenomenon, apparently existing only when the difference between allelomorphs is of a certain kind, and its presence or absence has no bearing whatever upon the fundamental Mendelian idea, namely, that of unit-factors which are constant (save for mutation), and are capable of segregation and of some degree of independent recombination. His statement that segregation is not always complete appears to be based mainly on the bar-eye case mentioned above. Other examples which he cites depend upon multiple and modifying factors, the very existence of which he apparently refuses to accept.

Finally, Prof. Paton quotes with approval, as in favour of his views and against those of Morgan's, Johannsen's words: that when we find "one single genotypical point of difference between them [*sc.* two organisms], this difference may probably consist in an alteration of the 'chemism' at a special point of the chromosome. . . . . ." However, this view of Johannsen's is precisely what not only I for one, but Morgan himself, finds most probable (see the close of Morgan's latest book, "The Theory of the Gene").

I have dealt with these points at length because they involve grave misconceptions; and it seems to me a serious matter that such misunderstandings, appearing under a name so deservedly distinguished as Prof. Paton's, should be allowed to interfere with the progress of biology.

There is no doubt in my mind that the next great step in biology will be the linking up of genetics and physiology via the analytic study of development. But this step will be sadly delayed if physiologists persist in misunderstanding genetics and in substituting for its clear-cut achievements such nebulous phrases as Prof. Paton's 'hereditary inertia' in place of the definite hereditary gene-complex, or fluctuating 'lines of metabolism' in place of the constant chemical units or genes, that segregate at reduction.

As final illustration of the inadequacy of the one view and the adequacy of the other, I will cite one further example. Prof. Paton prefers the view (against all the cytological evidence for chromosome continuity, especially of McClung, Miss Carothers, and L. V. Morgan) that chromosomes are "developed as the result of the metabolism of the cells." An acquaintance with the literature, however, would show that this is entirely negatived by the Drosophila results with haplo- and triplo-IV chromosomes, and by all the numerous results on supernumerary chromosomes in plants, notably Gates's on Oenothera and Blakeslee's on Datura. Further, in respect of the sex-chromosome, it is put out of count by the Drosophila results on gynandromorphism; and especially by the results of breeding from animals whose sex has been reversed, these *retaining* the original chromosomic constitution (as shown by the sex-ratio of the offspring: Crew and Witschi in frogs, Goldschmidt in moths, and Crew in fowls) in spite of the metabolic and functional change.

With reference to the inheritance of acquired characters, Prof. Paton is equally uncritical. He accepts Pavlov's preliminary communication on mice, for which no full paper with protocols has ever been published, but omits to mention the fully documented contrary results of Vicari and of McDowall. Alytes of course is adduced; on this point I would refer him to Dr. Noble's article in NATURE of August 7. Finally, he quotes Tornier's work on goldfish. Now, if he had looked up Tornier's original paper (he does not quote the reference—it is *Sitzb. Ges. Naturf. Freunde*, Berlin, 1908), he would have seen that Tornier has never conducted any genetic experiments at all. Tornier has shown (what we all knew before) that fish and amphibia raised under unfavourable conditions produce monstrosities; but he has never raised even an F1 generation from these animals, nor has this been done by his pupil Milewski, the only other worker who has essayed to extend Tornier's results. It should surely by this time be universally agreed that we cannot possibly distinguish what changes and characters are somatic and what are germinal until we have tried the test of breeding. As they stand, Tornier's results have no bearing one way or the other, either on genetics or on evolution.

Any stick will do to beat a dog with, so this *petitio principii* of Tornier (and, following him, of MacBride) is used in support of Lamarckian views. When it comes to the other side of the picture, however, we find Prof. Paton solemnly adducing Yule's analysis of Darbishire's pea figures as a proof that the law of segregation is not valid. I have referred to the original paper in the *Journal of Genetics*. In the crucial results, four classes are expected, in the percentage proportions 56·25, 18·75, 18·75, 6·25. In the material as a whole the actual proportions are 56·6, 18·9, 18·7, 5·9. They are 56·8, 21·2, 18·2, 4·8 in the 'worst' sample. Would any physiologist regard these figures as a bad fit? Yule has shown, it is true, that the divergences are statistically significant, but a slight acquaintance with genetic literature would show that numerous divergences of much greater magnitude may exist, but have been shown to depend on physiological differences between the zygotes (as when one type is less viable) or between the gametes or gametophytes (as when one type of pollen-tube grows faster than another, *e.g.* Renner's beautiful work on Oenothera). To deny segregation on the basis of such facts is on a par with denying any validity to the principle of the reflex arc, because in Nature the isolated or unmodified reflex arc does not exist.

Passing now to the rest of the book, we find some interesting chapters on reproduction, and especially on the relations of the endocrines to the gonads and to growth. The chief criticism I would urge of these chapters is that the student will be left with a somewhat chaotic impression. It is doubtless impossible to lay down such clear-cut principles as regards endocrine interaction as are possible in genetics. None the less, it would have been illuminating to have put forward frankly provisional views along the lines indicated by so many endocrinologists, showing the probable reinforcements and antagonisms of the various ductless glands.

Further, we miss any discussion of the question whether the reproductive and other hormones are chemically similar in all vertebrates; of the specificity of tissue responses to hormone action; of Keith's principle; and of the relation of hormonally-induced differentiation to that brought about within the cells by chromosomes (as in the sex-characters of insects). None the less, this part is a useful compendium of facts, and, if somewhat expanded, would be of considerable value.

There is an undue proportion of misspelt proper names, and an irritating irresponsibility in the matter of giving references, some being given, others of equal importance being omitted. A number of minor errors should be corrected. The frog has no organ of Bidder (p. 66). Drosophila is the *pomace*—not the 'pumice'—fly (p. 46). Pp. 71, 173, Inachus is not an example of alternating sex. It reverts in the non-breeding season to an 'infantile' or, better, neutral condition, exactly as do many small mammals in winter.

On p. 82 Prof. Paton repeatedly refers to "the passage from parthenogenic to sexual reproduction," apparently as if this had been the actual course of evolutionary events. Most biologists would certainly uphold the contrary view, that parthenogenesis is secondary. P. 157: if the author is so particular about *thyreoid* as the etymologically correct spelling, why does he use the hybrid and unfamiliar word *somal* for *somatic* throughout the book? P. 85: the term *sex-limited* for *sex-linked* should be dropped, since it is a misnomer. P. 92: the number of chromosomes and type of the sex-chromosomes of man is no longer in serious doubt, as Prof. Paton avers, since the publication of Painter's papers. I saw Painter's beautiful preparations in the University of Texas in 1924; there are 48 chromosomes, with a highly dissimilar XY pair in the male. P. 23: in quoting the experiments of Sumner (misspelt Summer throughout), who obtained an alteration of bodily proportions in young mice by exposing their parents to low temperature, Prof. Paton states that this must be an effect of the soma upon the germ cells. He does not seem to be aware of the elaborate and conclusive experiments of H. Przibram, who showed that the internal temperature of rats is altered by about 0·2° C. for every alteration of 5° C. in external temperature, and proved that changes of proportions in the offspring such as those observed by Sumner were in point of fact direct effects of change of maternal body-temperature upon the developing embryo.

Such examples only go to show the difficulty nowadays of an investigator who has specialised in one field seeking to master and to criticise results in another field—the difficulty, in other words, of effecting the synthesis that is so desirable.

Prof. Paton's book is, it appears to me, a failure chiefly because he has tried to be destructive without full comprehension of the principles or knowledge of the facts in the branch of science which he has attacked. If he would but collaborate with a geneticist to help us towards an understanding of the interrelations between genetic factors and endocrine (and other) modifiers of development, it would be a more fruitful task, in which he would be eminently qualified to achieve valuable results.

J. S. HUXLEY.

Fuel Utilisation.

(1) *Fuels and their Combustion.* By Prof. Robert T. Haslam and Prof. Robert P. Russell. Pp. xiv+809. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1926.) 37*s.* 6*d.* net.

(2) *Industrial Stoichiometry: Chemical Calculations of Manufacturing Processes.* By Warren K. Lewis and Prof. Arthur H. Radasch. (Chemical Engineering Series.) Pp. xi+174. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1926.) 12*s.* 6*d.* net.

(1) THE question of the economical use of fuel is becoming steadily more insistent, but the problems involved are far from simple. Most text-books on the subject deal only with some aspects, and there is a distinct need for a text-book giving a general

view of the whole subject, descriptions of the various natural fuels, the principles underlying their use for different purposes, together with examples of how these principles are applied in practice. The book by Profs. Haslam and Russell is intended to fill this gap, and does so with success. It deals with many points on which information is not readily available, and the fact that it is written for use in America, though it detracts to some extent from its usefulness in Great Britain, enhances its interest in other respects. It makes very clear the complexity of the problems involved in the economic use of fuel and the necessity both for further research and the better dissemination of the knowledge already existing.

One of the most noticeable facts brought out by a study of the book is the confusion that is liable to result from the multiplicity of units in use. The chemist thinks in the metric system of units and degrees Centigrade; the industrialist and engineer generally think in pounds, feet, and degrees Fahrenheit. As an example of the lack of system prevailing, the following energy units, which are all in use, may be cited: British thermal units, pound-centigrade units, calories, foot-pounds, kilogram-metres, horsepower-hours, kilowatt-hours, and Joules. To make matters worse, 'Standard Temperature and Pressure,' when considering measurements of gases, are 0° C. and 760 mm. of mercury, but the normal conditions under which gas is sold, and the legal conditions in Great Britain, are 60° F. and 30 inches of mercury. The authors steer ably through the resulting maze, but the unnecessary confusion of units undoubtedly retards progress in fuel economy. The English reader of an American book must further remember that the American 'ton' is 2000 lb. and the American gallon only 8·33 lb. of water, while the Imperial gallon is 10 lb.

The book deals first with the occurrence and nature of the natural fuels, solid, liquid, and gaseous. Analyses are given of many typical American coals, and various proposed coal classifications are considered; the Seyler classification, however, found so useful in England, is not mentioned. There is still much to be learned on the spontaneous combustion of coal and the changes that take place during storage; this is well brought out in Chap. iv., which gives a good account of present knowledge and practice.

The chemistry of the reactions occurring during combustion is dealt with more fully than usual, and the equilibrium conditions, velocity of reactions, flame temperatures, and the factors affecting them are clearly dealt with. Useful tables are included of the heats of reactions, specific heats, sensible heat in gases at various temperatures, and many of them are plotted as graphs—in some cases the data are given only in the form of graphs. It is a pity that these graphs, some of them of great practical use, are reproduced on so small a scale. The numerical examples given to illustrate their use quote data, as obtained from the graphs, to an accuracy quite unobtainable from the reproductions. Many numerical examples are given of combustion calculations, but these would frequently have been easier to follow had the authors been less afraid of using algebraic symbols. After dealing with theory, examples are given of practical applications to boilers and furnaces, and sufficient details of typical plants, both of American and European type, are given to illustrate current practice, and to emphasise the widely varying importance of the different factors involved according to the requirements of the various industrial processes.

The properties and methods of manufacture of producer gas, water gas, oil gas, coal gas, and coke are all considered. The chapter on carbonisation of coal is excellent, but it is somewhat surprising that the work of the Fuel Research Board on steaming in vertical gas retorts, and on carbonisation at 'low' temperatures, is neither mentioned nor referred to in the bibliography. It is clearly brought out that chemical analyses give little indication of the coking properties of a coal, and though results of various British workers are quoted, and several laboratory tests for coking properties are mentioned, no reference is made to the Gray-King assay apparatus developed for the Fuel Research Board, and found so useful by them and other workers in England.

It is frequently forgotten in text-books and academic discussions that commercial efficiency and thermal efficiency are two distinct things; an increase of thermal efficiency may indeed sometimes only be obtainable by actually increasing the cost of the service required. This is well brought out in many places in the book, and examples are given of how to determine the most economical design and method of working under given conditions and with a given fuel. These are valuable in driving home the fact that the most economical method to adopt depends on a host of factors which vary greatly with local conditions. At the same time, there is sometimes a tendency to generalise from insufficient data, probably because really adequate data are not available.

The authors have apparently felt it desirable to assume that the reader has no knowledge of mathematics beyond simple arithmetic, until they come to the discussion of the flow of liquids and gases, the flow of heat, and the rate of heating, which are well dealt with, but relegated to appendices. One feels that, at any rate for the English student, and one hopes for the industrialist, a knowledge of algebra could have been safely assumed with advantage to the explanations.

Apart from the small size of some of the graphs, and a few misprints, the book is well produced, and the difficult problem of apportioning the available space to the different subjects dealt with has been well solved. A bibliography at the end of each chapter gives references to the authorities quoted, and indicates where further information can be obtained.

(2) This book is in quite a different category from the preceding; it is a classroom text-book which deals with chemical calculations in industrial processes. So far as combustion is concerned, it covers some of the ground dealt with in (1), but extends also into other chemical processes. Copious numerical examples are given, together with problems to be worked out by the student. In a table of constants at the end appears the statement that "one gallon of water" is "8·33 lb. per cubic foot," a rather alarming misprint to occur in a text-book of this nature.

A Popular Work on Tides.

The Tide. By H. A. Marmer. Pp. xi+282+4 plates. (New York and London: D. Appleton and Co., 1926.) 10*s.* 6*d.* net.

THIS excellent book is written by the assistant chief of the Division of Tides and Currents of the U.S. Coast and Geodetic Survey. It gives an account of the subject of tides intended for the general reader and without the use of mathematics. Its chapters cover the development of tidal knowledge, the tide-producing forces, the characteristics of observed tides in rivers, bays, and the open sea, the effects of wind and weather, the analysis of observations, the making of tide-tables, the utilisation of tidal energy, and the evolutional effects of tidal friction. Special chapters are devoted to the tides of the Bay of Fundy and of New York Harbour.

The book is written with remarkable accuracy, lucidity, and force, and should find few readers who cannot master its contents. In kinematical and dynamical explanations the aims of the author are very modest, many relationships being referred to the authority of the mathematicians. Nevertheless, numerous simple calculations are given regarding the mechanics of actual tides, and these throw much light on the subject.

To explain the making of the tides in 'the seven seas,' a sketch is given of some of the principles underlying the theories of R. A. Harris, and one is bound to admire the way in which on this subject the author has kept within the justifiable. The cotidal charts of Harris have been wisely omitted, but an explanation of the meaning of a cotidal chart would have fallen easily within the scope of the book. As is natural, the illustrations are taken chiefly from the tides of the New World, but an exception might well have been made for one of the well-attested cotidal charts, which happen to belong to the Old World, especially as these always prove so interesting to those unfamiliar with the subject. No mention, however, is made of the results of the sort of work in this connexion on which R. Sterneck and A. Defant have been continuously engaged since about 1910, though the introduction asserts that the book refers more especially to the results of recent investigations.

It is curious that in describing the action of the tide-predicting machines the amplitude of the curve for a single harmonic constituent is stated (p. 197) to be equal to the length of the crank-arm instead of double this length. The printing and general appearance of the book are very good, but two lines have got interchanged on p. 168. Also, in the reviewer's copy, pp. 275-280 are unfortunately omitted; they include the end of the text and much of the index.

Perhaps it may be of interest to compare the book with the well-known non-mathematical work of Sir G. H. Darwin. The two are very different; that of Darwin reflects the dynamical researches of a great cosmogonist, while the present volume reflects the work of a member of a national survey. Much of Darwin's book is not immediately concerned with ocean tides, but with kindred phenomena of the solar system, and lies outside the scope of Marmer's book. J. P.

The History of Fishing.

Fishing from the Earliest Times. By William Radcliffe. Second edition. Pp. xxi+494+22 plates. (London: John Murray, 1926.) 21*s.* net.

MR. WILLIAM RADCLIFFE'S interesting volume upon the history of the fisherman's craft received a well-deserved welcome when it was first published in 1921, and was accepted at once as an attractive and instructive contribution, filling an important gap in the literature of the subject, voluminous though this literature already was. We may rejoice with the author over the success of the first edition, as evidenced by the advent of a second. Actually, little needs to be said in regard to this new edition, since it differs but slightly from the earlier. The new volume is in fact a reprint with sundry minor alterations and emendations. The pagination remains the same, and the alterations have been governed by the necessity of making the new passages conform exactly to the spaces occupied by the discarded ones. This, no doubt, has been considered imperative, but one cannot but realise that the emendations would have proved more satisfying had these limitations not been imposed.

The author, in his preface to the new issue, deals briefly and disarmingly with some of the criticisms applied to the first edition, but one feels that those criticisms would have been more ably and fully met had the author been given a free hand to re-write some of the passages, instead of trimming them with carefully equated verbal modifications, which do not completely succeed in spiking the critics' guns. Thus, the passages relating to Aristotle as the earliest 'scale reader' might have been so rendered as to differentiate more satisfactorily between the shell laminæ of the mollusc and the scales of a fish, which belong to such different structural categories. Also, in regard to his including dolphins among the fishes, one would feel more appeased by the added footnote on p. 90 had he applied inverted commas to the word *fish* whenever it functions for the cetacean. Aristotle himself was at pains to differentiate dolphins from fishes, and thus early set a good example.

The '*pattern* of Torpedo fish' identified by the author upon the Campanian plate (p. 180) has in the new edition been reduced to *one* Torpedo fish; but he still does not enlighten us as to which individual in the group *is* the fish in question. The prominent figures represent clearly three teleostean fishes and one squid (decapod mollusc). There remains, on the right-hand margin of the plate, a small indefinite figure; but, if *this* is the Torpedo-ray, it is a very unconvincing portrayal, scarcely justifying the inclusion of the whole-page illustration.

Mr. Radcliffe refers in his new preface to the lengthy correspondence and controversy which was stimulated by his disquisition upon the κέρας βοὸς ἀγραύλοιο of the "Iliad." He adds yet another suggestion, based upon an epigram by Quintus Maccius, though it is very hard to see how this may help in the solution of this interesting and elusive problem. One would have welcomed from him a judicial summing up of the case, in the light of all the suggestions hitherto offered, but this clearly was not possible without playing havoc with the existing pagination. But one or more appendices might have been added and the interest and authority of the new edition might thus have been further augmented. The feasibility of such added appendices is, indeed, exemplified by the useful and welcome bibliography which appears as a new feature in the second edition. This bibliography does not profess to be exhaustive, but gives a complete list of authorities referred to by the author in his text. The index could still be expanded and revised with advantage, and in the text of the volume sundry misprints and slips seem to have been inherited by the second from the first edition.

Many readers may still cavil at Mr. Radcliffe's chosen definition of 'Angling' as "the action, or art, of fishing with a Rod" (p. 47), and, in spite of his interesting statement of the case, will prefer to retain 'fishing with a Hook' as more nearly in keeping with such etymological evidence as is available. But a subject which includes no debatable items risks being a dull one, and Mr. Radcliffe is the last person to allow any subject of which he treats to be dull; so, while casting a few friendly 'lures' over him, to induce a 'rise,' we offer to him a second edition of our thanks in welcoming a second edition of his important, suggestive, and entertaining book.

H. B.

Our Bookshelf.

Physico-Chemical Methods. By Prof. J. Reilly, Prof. W. N. Rae, and Dr. T. S. Wheeler. Pp. xi+735. (London: Methuen and Co., Ltd., 1926.) 30*s.* net.

THE task of providing an English substitute for the well-known "Handbuch und Hilfsbuch" of Ostwald is a formidable one, if only because the latter volume has had thirty years' start, with the further advantage of revision and expansion in successive editions during that period. The present volume must therefore be regarded as the beginning rather than as the completion of a new enterprise.

Nevertheless, a first reading of the book gives an impression of unexpected completeness, and suggests that the authors have perhaps checked their own table of contents against those of other works of a similar character, in order to avoid the type of omission which may be revealed more clearly by practice than it can be foreseen by theory. Thus a careful search through several sections has been required to discover the possibility of supplementing the text by including descriptions (1) of the home-made glass Bourdon gauges which are now used for measuring the pressure, *e.g.* of corrosive gases; (2) of the method of measuring low pressures by observing the rate of cooling of a hot wire and (3) of Rast's method of determining molecular weights with an ordinary thermometer by observing the large depressions of the freezing-point of camphor. The apparatus used by Adam for measuring the lowering of the surface tension of water by the addition of films of oil is also sufficiently practical to be included in a volume of this kind. On the other hand, the methods of X-ray-analysis of crystals are so difficult to master that one may reasonably question whether a chapter of 23 pages can be of any real value to a beginner who wishes to undertake work of this kind. The inclusion of a chapter in colloid chemistry is much easier to justify, although it is scarcely possible for such a chapter to compete successfully with books which are devoted entirely to this subject.

The book is well illustrated, but a mistake has been made in reproducing some of the figures on a far larger scale than is necessary; in particular the diagram of a burette tap on p. 168 is singularly out of proportion to its importance. Better results could probably have been obtained if the number of writers had been increased to such an extent that each chapter could be entrusted to an author specially selected for his experience in the particular type of measurement to be described; but, leaving this possibility out of account, the three authors of the present volume may be congratulated on the measure of success which they have already attained in covering, by their joint efforts, the wide field of physico-chemical measurements.

Food, its Composition and Preparation: a Textbook for Classes in Household Science. By Mary T. Dowd and Jean D. Jameson. Second edition, revised. Pp. x + 177. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1925.) 7*s.* 6*d.* net.

THIS book is intended to supplement notes of students attending domestic science classes, and deals with the theory of food as applied to the kitchen and the household. A general outline of food and its physiological functions comprises the first chapter, which is followed by a discussion of water and its use as a cooking medium. The chapters on carbohydrate deal with the subject from the viewpoint of sugars and starches in such a way as to obscure their connexion in diet unnecessarily. Thus while it is admitted that sugar is mainly a source of energy to the body, "starch plays a most important part in the construction of body tissue," on account of its "nucleo-protein." Such is, unfortunately, typical of some of the chemistry of the book, which should be corrected in the event of another edition being forthcoming.

Tables are given of the time required for cooking various foods, although actual recipes are withheld, as the authors feel that each teacher will prefer to introduce her own. Bread-making is, however, explained in detail, and throughout the book little points are clearly defined, the omission of which frequently spoils what is otherwise excellent food. The use and preparation of the protein foods occupy five chapters, under the headings of milk, eggs, meats, poultry and game, fish. The directions for planning menus, and the combination of foods in meals, are well presented, although based upon American usage, which has little differences from those generally adopted in England. Thus, after a meatless breakfast and luncheon, dinner is left to complete the total daily allowance of 2500 calories, about one-tenth of which are to be derived from the mayonnaise dressing on our salad to be served with our ration of "two thin slices" of roast beef.

The book has the merit that it never allows the student to lose sight of the cost of the different foods. This is achieved by a list of suggested experiments and examples for laboratory and kitchen practice at the end of each chapter. The book is well illustrated and contains a glossary of the principal terms used.

British Snails: a Guide to the Non-Marine Gastropoda of Great Britain and Ireland, Pliocene to Recent. By A. E. Ellis. Pp. 275 + 14 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1926.) 10*s.* net.

"THE want of a handy work of reference, giving in a convenient form descriptions and figures of all the British non-marine Gastropods," inspired the author to attempt the present publication. He has, wisely we think, included in his scope some forms, such as *Littorina neritoides*, *Otina otis*, and *Onchidiella celtica*, that dwell just above high-water mark and are apt to be omitted by writers on the marine forms on one hand and on non-marine on the other. For an obviously first endeavour this book is a remarkably successful and well-written piece of work, and it will prove of very great use to those for whom it is intended. No pains have been spared to make it complete and the net of research has been thrown wide. Still one cannot but regret that the author did not stay his pen until he had acquired more extensive first-hand knowledge of his subject. There are minor errors and slips on every page from the first, where rhinophores are treated as if synonymous for tentacles, down to the last, where the bracketing of the geological formations has gone all wrong. By the time, however, that a second edition is called for, the author will probably have realised this and rectified matters.

The introductory portion treats briefly and wisely, in an elementary manner, the structure of the snail, the classification of the mollusca, the origin of the non-marine mollusca, and further includes a "Synopsis of the Genera" which takes up space that might have been far more profitably employed. There are fourteen plates, which, save the two illustrating the slugs, are half-tone reproductions of photographs taken by the author's father. As photographs they are remarkably good, and far surpass Rimmer's first essay in this mode of illustration in 1880, while the originals must have been even finer. As illustrations from which to name species, however, they cannot be deemed a success, while some are for that purpose useless. This, though, is the fault of the sitters and not of the photographer. The text illustrations are unexceptionable, while the get-up of the whole book is only what one expects from its publishers, and no higher praise than that is possible.

Handbuch der Experimentalphysik. Herausgegeben von W. Wien und F. Harms. Band 1: *Mess-Methoden und Mess-Technik*, von Dr. Ludwig Holborn; *Technik des Experiments*, von Dr. Ernest von Angerer. Pp. xx + 484. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1926.) 42 gold marks.

THIS handsome book with its large pages, clear type, and numerous illustrations, has a very attractive appearance. It forms the first volume of the important 'Handbook' of experimental physics now in course of publication in Leipzig. The editors state that it appeared desirable to place in the forefront of their work a summary account of physical measurements and the technique of experimentation. It would be unfair to criticise the scope of the work in the absence of the later volumes, as it forms only the first part of a complete whole.

Dr. Holborn, the author of the first section (on methods of measurement), has had no easy task to perform in having to avoid, on one hand, the mere reproduction of an instrument-maker's catalogue and, on the other, the supply of information to be found in any text-book of practical physics. He has been limited to a description of the more fundamental methods, since it is obviously impossible, for example, to give an exhaustive account of the measurement of electrical resistance in some ten or twelve pages. We could, however, have wished for a more critical discussion as to the relative merits of different methods.

The experimental physicist has to carry out or superintend the construction of many kinds of apparatus, and it is necessary for him to be familiar with many mechanical processes and the properties of various materials. In the second section of this book he will find much useful information as to the characteristics of metals, solders, and cements, the working of glass and the deposition upon it of thin metallic layers. Hints are given on such widely different topics as the preparation of vacuum tubes and the choice and treatment of photographic plates. It is only by actual trial that such instructions can be tested, but so far as can be judged, they are just those which the experimenter is likely to require. The information seems well up-to-date, and where necessary, references are given to books in which further details of methods and processes are to be found.

Crop and Stock Improvement. By A. B. Bruce and Dr. H. Hunter. (*The Farmer and Stock-Breeder* Manuals.) Pp. 119. (London: Ernest Benn, Ltd., 1926.) 5*s.* net.

THE authors have succeeded in presenting, in the form of a readable story, an account of the methods used in the improvement of plants and animals, and the results achieved thereby. So far as possible the story is told in simple, non-technical language, but does not suffer in accuracy on this account. The historical method is followed, and throughout the book the attitude of the authors is refreshingly critical.

In the plant section Dr. Hunter deals first with improvement by selection, then with the work of the hybridisers, pre- and post-Mendelian. A long chapter is devoted to a description of the results which have been achieved, and there is an excellent final chapter on the distribution of improved strains of crops.

Mr. Bruce's treatment of the improvement of animals, on account of the much greater complexity of the subject, is necessarily more general. The first chapter describes the main principles of Mendelian segregation. In the second and third chapters are discussed the methods by which the present-day improved breeds of farm animals have been produced. The last chapter is devoted to an examination of the methods and use of inbreeding.

The book is commended to all those who are interested in agriculture, whether students or farmers or both. It will give them a measure of the results which have been achieved in the past, and a basis on which they may estimate what further improvements may be hoped for in the future.

Chemistry of the Proteins and its Economic Applications. By Dr. Dorothy Jordan Lloyd. Pp. xii+279. (London: J. and A. Churchill, 1926.) 10*s.* 6*d.* net.

THIS volume, bearing, as it does, an introduction by Sir Frederick Gowland Hopkins, is developed from a series of lectures by the author. The subject naturally falls into two main parts, the chemical constitution and the physical chemistry. The first part, after dealing in a general way with the composition of the protein molecule, proceeds to outline one or two of the more usual methods of analysis. A full discussion of the use of the amino acids from the physiological point of view is followed by a chapter on the problems of food preservation. It cannot be claimed that this part of the work offers more than a compilation of material already available to the student or general reader. The second part is devoted to a systematic discussion of the physical behaviour of the proteins so far as research has been carried. The results of Loeb, Cohn, and others are dealt with side by side and compared in such a way that their study will be repaid by a grasp of the different aspects of the subject by any student already possessing fundamental knowledge of physical chemistry. The value and importance of the physical chemistry of the proteins are well illustrated by the chapter on the "Industrial Uses of the Proteins," which could with advantage have been extended. Each chapter bears a bibliography, which, while not quite complete, gives reference to most of the fundamental research on the subject.

Adventures of Exploration. Book 5: *Australia and New Zealand.* By Sir John Scott Keltie and Samuel Carter Gilmour. Pp. iv+204. (London: George Philip and Son, Ltd.; Liverpool: Philip, Son and Nephew, Ltd., n.d.) 2*s.* 3*d.*

THE fifth volume in this series is even better than the earlier ones. The material has been chosen with so much care and the stories told with such admirable lucidity that no one reading the volume can fail to get a well-balanced general view of the stages by which Australia, New Guinea, New Zealand, and South Victoria Land became known and were explored. After some account of early voyages of discovery, there are chapters on the work of Cook, Bass, and Flinders, the overland journeys of Oxley, Stuart, Eyre, Grey, Burke, and others in Australia, followed by chapters on New Zealand and Papua. The book closes with two chapters on the Antarctic, giving accounts of the work of Scott, Amundsen, and Shackleton in the Ross Sea and Mawson in Wilkes Land. There are a number of well-chosen illustrations and portraits, and every chapter has its own map. The series should be a valuable aid in teaching school geography.

Immunochemical Studies. Edited by Prof. Carl H. Browning. Pp. xiii+239. (London: Constable and Co., Ltd., 1925.) 12*s.* 6*d.* net.

IN this small volume the editor has gathered together a series of papers published by himself and his collaborators over more than a decade. The matter has been rearranged to make it suitable for book form. The work is entirely on the humoral aspects of immunity. The first chapter gives an excellent short account of antibody action in general: among the subjects dealt with in the succeeding chapters are the antigenic power of globin, the alterations which occur in hæmolytic immune bodies during the process of immunisation, heterophile antigen and antibody, and complement. The section on the latter contains a certain amount of matter which has not hitherto been published. The work will appeal to those interested as giving in handy form information which is scattered in a number of different volumes.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Fayum Lakes.

THE first of six reasons given by Sir Flinders Petrie (NATURE, Oct. 9, p. 514) for maintaining his view that the level of the Fayum lake gradually rose with the rise of the Nile, is that there must have been an open channel which it is unlikely would have become blocked when a large mass of water flowed to and fro each year The flood waters of the Nile are heavily silt laden, and when they entered and filled the Fayum the surplus would have re-established its ordinary course northwards along the valley. The lake, connected by a channel at least 10 kilometres long, would never have filled quite to the highest flood level of the river. As soon as the crest of the flood passed and the water levels began to fall, the current in the connecting channel would die away, silt would be deposited, and it would have become choked and blocked up. The river carries most silt at the highest levels of the flood, and the rapidity with which deposits are formed must be seen to be realised The inlet, once closed with a bank of silt, would not have been readily reopened.

Such conditions are illustrated by many depressions bordering the Blue Nile between Singa and Roseires. They are minute in comparison with the Fayum, but the same principle doubtless applies

Under organised government, the connecting channel could have been kept open and the annual influx and efflux referred to by Sir Flinders may have been maintained, the lake being subject to a range of levels depending principally on the height of the Nile flood, the efflux, and evaporation Under natural conditions, on the other hand, when the connecting channel had been closed by silt, communication would not have been re-established until either erosion cut away the bank or an exceptionally high flood occurred. In our own times there have been the very high floods of 1874 and 1878, had such floods silted an inlet channel, several decades might also have passed before communication could have been re-established Sir Flinders Petrie remarks that complete drying up would occupy only about twenty-five years. It is for such reasons that it is difficult to understand how lakes with fairly stable water-levels could have been maintained in the Fayum under the conditions we know in the Nile Valley to-day, which have certainly prevailed over a large part, if not the whole, of historic times.

Another factor which might influence the relations of the Nile to the Fayum is the position of the sea-shore and consequently the slope of the river in the intervening distance. We know that the Delta has been subject to earth movements, and in fact Sir Flinders was understood to say in his contribution to the discussion that it had fallen about 30 ft. before Ptolemaic times, when it rose about 15 ft. It may be readily supposed that a fall of 30 feet at the Delta shore might have led to considerably increased slopes and a consequent incising of the river bed affecting conditions at least so far as the neighbourhood of the Fayum, which is about 110 kilometres upstream of the apex of the Delta. This is a second reason for doubting the view that the Fayum lake-levels belong to a simple progressive series.

The levels under consideration are as follows :

	Feet above Birket Qarun	Metres, referred to mean sea-level, Alexandria	W F.P dating, submerged since
Present Nile flood .	243½	+29	
Present valley floor .	237	+27	
High-level lake . .	222	+22·5	
Neolithic lake . .	205	+17·4	
Implements on gravel	185	+11·3	8,000 B C
Flints	176	+ 8·5	9,000 B C.
Lake	160	+ 3·6	
Prehistoric pottery .	156	+ 2·4	14,000 B C
Pigmy flints and cores	138	− 3·0	17,000 B C
Present Birket Qarun.	zero	−45·1	

If the Nile now had unrestricted access to the depression, the resulting lake, depending on the connecting channel cut through the Nile flood plain, might be expected to stand at about 25 or 26 metres above sea-level. The dates have been culled from *Ancient Egypt*, March 1926, where they were added by Sir Flinders Petrie In reducing the levels given there, he adopted − 144 ft. as that of Birket Qarun, while in the papers presented at Oxford − 148 ft has been used.

Sir Flinders evidently considers that the lake-levels have been gradually rising for a very long period of time. Have we any justification for supposing that the same steady rise has extended so far back into prehistoric times ? The definite lake margins recorded by Sir Flinders' assistants appear to oppose his theory of a gradually rising lake.

It seemed generally agreed by those who had studied the subject in the field that the lake which stood at 22·5 m. above sea-level was of very much older date than the 17·4 m lake associated with the neolithic remains. Sir Flinders in his reply did not refer to the date of this higher lake He has doubtless given the evidence very careful consideration, and it would be of interest to know how he fits it into his scheme of dates. It appears that the fauna of the 22·5 m lake, while distinctly Nilotic in character, shows certain differences when compared with the 17·4 m. lake, and also that the deposits associated with the higher lake were consolidated and eroded before the 17·4 m. lake came into existence.

Among the six reasons given by Sir Flinders for maintaining the view that the levels of the Fayum lake gradually rose, the fourth, stating that there is no trace of human work anywhere below the Nile level of its own age, makes the strongest appeal. May this not be due to the fact that the dried-up floor of the depression attracted no inhabitants in the intervals between the lakes, and also because any remains are hidden from us by deposits of silt ? Even if Herodotus did see the water flowing to and from the lake of his time, and the quays of late origin were made for a lake that stood at 215 ft, it does not necessarily follow that the early lakes belong to the same progressive sequence. We can accept, too, what Sir Flinders gives as his third reason, namely, the discovery of a cooking pot, fire, and flints *in situ* at 170 ft. level, and that these were submerged by a lake in Greek times, again without need to suppose that the levels rose progressively from one to the other. The two lakes may have been quite independent The remaining point as regards the water that filled the lake being from the Nile has no direct bearing on the sequence of levels.

The band of brilliant workers who have been studying the ancient history of the Fayum and the Nile valley, stimulated by Sir Flinders' leadership, have established a number of facts, among them the existence of definite lake margins. The researches are admittedly incomplete and further developments, besides elucidating the sequence of the lakes, may show during what lengths of time they existed and what were the conditions that allowed the water to remain steady for those periods. While some of the facts do not seem to fit the older ideas, it might be better to hold those theories in suspense

Turning to another aspect of Sir Flinders' letter, the epithet of unfortunate irrelevance seems severe to apply to the remarks contributed about the character of the implements. Has not Sir Flinders figured implements from the Fayum as Solutrean (*Ancient Egypt*, 1915), and remarked on their close equivalence to the Solutrean of Europe, basing his comparisons largely on a group which he tells us were selected at a dealer's from among the contents of a barrel?

G. W. GRABHAM.

Khartoum, November 3

Laue-Photograph taken with a Long Slit.

ORDINARY metals are composed of aggregates of small crystals. These small crystals may be made to grow, by suitable processes, to very much larger ones, so that we can obtain a test piece of proper size composed entirely of a single crystal of a metal. Such test pieces of single crystals of metals do not, as a rule, possess plane faces, that is, the external forms of crystals, but X-rays afford us a means of determining the orientations of the axes of such crystals. A. Muller (*Proc. Roy. Soc.*, London, 1924) photographed the Laue-spots at various orientations of the specimen, and from the position of the characteristic *K*-radiations of the anticathode on the photograph, he determined the orientations of the axes of the crystal. Next, T. Fujiwara (*Mazda Kenkyu Jiho*, Tokyo Electric Co., 1926) achieved the same purpose by finding the characteristic *K*-radiation in some of the ordinary Laue-spots; while H. Mark, M. Polanyi, and E. Schmid (*Zeit. fur Phys.*, 1923), and K. Weissenberg (*Zeit. fur Phys.*, 1924) applied the method of rotating the crystals. All these authors employed a narrow and nearly parallel beam of X-rays, so that only a small portion of the specimen could be tested at one time.

In order to examine the whole of the specimen at once, we have utilised divergent X-rays starting from the focus on the molybdenum target of a Coolidge tube. These divergent rays were made to pass through a long narrow slit, and then to illuminate a long thin specimen composed entirely of a single crystal of aluminium. The Laue-spots thus became an assemblage of many lines on the photograph, as seen in the accompanying illustration (Fig. 1). Each one of these 'diffraction-lines' is a spectrum of the X-rays caused by reflection from a certain atomic plane of the crystal; any one point on one of these lines being registered by the X-ray of a certain wave-length, which is reflected from a part of the atomic plane of the crystal situated at a certain point of the specimen. Thus each point on any one of the diffraction-lines in the photograph corresponds to a certain part of the specimen. This correspondence is important, and we have made it recognisable on the photograph by the shadows cast by some thin wires of lead, which were stretched across the slit situated very near to the specimen.

When this correspondence and the data of relative positions of various parts of the apparatus are known, the orientation of the atomic plane of the crystal which caused a diffraction-line on the photograph, and the glancing angle of the beam of X-rays to this atomic plane, can be calculated readily at each corresponding point on the specimen. Moreover, for a diffraction-line on the photograph, on which the characteristic *K*-radiations of the target appeared, the indices of the atomic plane of the crystal which is responsible for that diffraction-line can be found easily. By knowing the values of the glancing angles at two points on the specimen which correspond to two shadow-points on the diffraction-line, the glancing angle for the *K*-radiation on the same diffraction-line can be obtained by interpolation. With this value of the glancing angle for the *K*-radiation, and wave-lengths of that radiation, the value of the grating constant, and consequently the indices of the atomic plane under consideration, can also be found immediately.

For the present purpose an X-ray tube with a sharp focus is preferable. The focus of the tube we used was not quite sharp, being about 5 mm. in diameter. We could, however, use it as a sharp focus—one of about 1 mm.—by setting it in such a position that the surface of the target is nearly, but not exactly at right angles to the slit.

With this apparatus we could determine the orientations of the axes of single crystals of some thin aluminium wires and of a fairly thick block of lead which had a nearly cylindrical surface. Single crystals of aluminium wires were made by H. C. H. Carpenter and C. F. Elam's method (*Proc. Roy. Soc.*, London, 1921). Their diameters were about 2 mm., and their lengths were not the same for all the specimens, varying from 4 cm. to 12 cm. With these specimens many diffraction lines were usually obtained in a single photograph, which contained the impressions of the *K*-radiations of molybdenum, as seen in the accompanying illustration. We have calculated the orientations of the axes of the crystal with reference to the co-ordinate axes fixed to the specimen by these several diffraction-lines. In the following table the angles between the axis of the wire and the three edges of the elementary cubic lattice of the aluminium crystal are given for six different crystals examined.

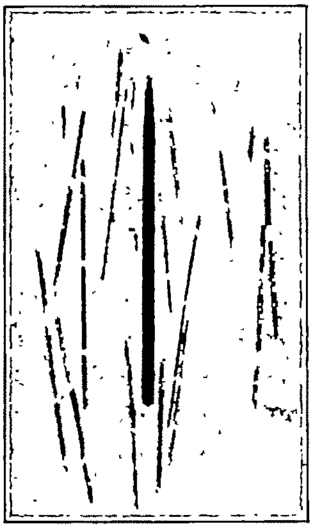

FIG. 1.

No. 1.	No. 2.	No. 3.	No. 4	No. 5.	No. 6.
87°	87°	85°	88°	89°	89°
62	57	65	63	61	61
29	34	26	27	28	30

Though it may be premature to state general conclusions here, it seems not out of place to note that these angles are nearly the same, and that one of the (100) planes of the crystal is situated nearly parallel to the axis of the wire, at any rate for all the six specimens tabulated above.

The present method of determining the orientation of the axes of crystals is very simple, and at the same time it shows very clearly on the photograph whether the specimen is composed of a perfect single crystal or not. So far we have applied this method to thin wires only, but it may equally be applied to thin plates or to any specimen which has a plane or cylindrical surface.

The Crystalline Nature of the Chief Constituent of Ordinary Coal.

AN examination of a microscope section of Indian coal from the Raniganj coal-field showed that the main substance of the coal was a madder-red coloured, translucent material, which in a section cut vertical to the bedding planes of the coal, gave faint pleochroic effects when examined in plane polarised light. The same substance, when viewed between crossed Nicols, had distinct extinction parallel to the lines of the laminæ and behaved like a uniaxial mineral. The peculiarity is that the whole of the red-madder substance, seen in the field of the microscope, behaved as though in optical continuity and as if part of a single crystal.

Eight slides, two each, one cut parallel to the planes of bedding and the other vertical to this direction, of so-called clarain, vitrain, durain, and fusain made by Mr. James Lomax of Bolton, were procured, and in the vertically cut sections the same phenomena are to be observed. In the sections cut parallel to the bedding the substance behaves as an isotropic mineral. The first six slides are of the thick coal of Exhall in Warwickshire, while the sections of fusain are of the Trencherbone coal of Lancashire.

These slides show that there is only one chief constituent in the coals examined, which for lack of a better name, one may speak of as vitro-clarain (after Stopes) or anthraxylon (after Thiessen). Scattered through the coal, usually along the planes of bedding, are sections of bright gold or red resinous matter suggestive of the sheaths or walls of sporangia, and smaller gold specks and lenticles which may be spores. In addition, there are red translucent patches of a rough, pitted nature, which might be the outer skin of sporangia, as some of these, cut obliquely, show a distinct cellular structure.

In the sections of durain the laminæ are rather closer together than in the slides of clarain, and the laminæ are well marked, as though with thin sheets of opaque inorganic material. The fusain is obviously associated with 'dirt' bands in which pyrite, siderite, and calcite can be distinguished along with the powdery carbon. In some cases a beautiful reticulated structure is evident in the fusain, as though the inorganic matter was an infilling in some organic structure.

Thus it appears, from a petrographic examination of the usual kind, that these coals consist of four components, but rather different from those identified by Dr. Marie Stopes. My components are as follows: (*A*) One main constituent which simulates a crystalline structure, and (*B*) three minor or relatively minor constituents—(1) resinous bodies, such as sporangia and spores which may be present in large or small quantities and may markedly affect the quality of the coal; (2) powdery, soft carbon with the macrostructure of charred wood, which is well known as mineral charcoal or fusain; and (3) inorganic matter—clay along the laminæ or scattered through the coal, as well as other such recognisable minerals as pyrite, calcite, siderite, etc., usually associated with the fusain. With this inorganic matter could be grouped the inorganic impurities, for example, ankerite, etc., which occur in cracks and joints in the coal.

The most important and certainly most uniform substance of these coals is the material, designated *vitro-clarain* in courtesy to Dr. Stopes, which constitutes the main bulk of good coal and probably represents the mineralised form of woody tissue. Its crystalline behaviour is strange, but will probably be fully accounted for by organic chemists as some kind of strain phenomenon.

CYRIL S. FOX.

Geological Survey of India,
Calcutta, September 23.

THE application of the petrological microscope to the study of coal sections may lead to interesting observations on the details of coal structure, and I am glad Mr. Fox is taking it up. It is a little unfortunate, however, that he should add to the complexities of coal nomenclature on so slender a basis as his observations on his first few sections.

In his third paragraph he writes as though "vitro-clarain (after Stopes)" were identical with "anthraxylon (after Thiessen)," a confusion which has already been exposed concisely by Seyler; see "The Nomenclature of the Banded Constituents of Coal" (NATURE, April 3, 1926).

In his fourth paragraph Mr. Fox describes "a beautiful reticulated structure" as being evident, "as though the inorganic matter was an infilling in some organic structure." This is a truism to students of coal, the "reticulated structure" being tracheids of woody tissue, generally the secondary wood of Lepidodendron, or Cordaitean trees, which constantly have crystalline matter filling the laminæ of the tracheids.

Mr. Fox's main point, however, that there is *one* main constituent which simulates crystalline structure in coal, is a suggestion which, if true, would have a very material bearing on the details of research into coal structure, and should certainly be checked by observations on much larger numbers and varieties of coal sections.

It must be borne in mind that, in general, the large bulk of bituminous coal contains ulmic compounds which are colloidal in their nature.

I must dissent from the phrase in the concluding paragraph that this ". . . constitutes the main bulk of good coal and probably represents the mineralised form of woody tissue" The major part of coal substances is not mineralised but mummified; and woody tissue is *one* of its constituents, but only one of many.

Adsorption of Dyes to Silver Halides.

THE quantitative determination of the amounts of dyes taken up by crystalline solids has both a general and special interest. The adsorption of dyes to silver halides, and particularly of sensitising dyes, has considerable photographic importance in relation to the theory of optical sensitising. Work has been in progress for some time in this laboratory on this problem by methods devised by the writer and Mr. H. Crouch. The dyes investigated are of the iso-cyanine and carbo-cyanine class, and the bulk of the work so far has been carried out with orthochrome T-bromide (*p*-toluquinaldin-*p*-toluquinoline-ethylcyanine bromide).

These dyes are decolorised at sufficient acidity, the colour being restored by alkali, and the colour change being sharp enough for the dye to be used as an indicator. The partition coefficient of the dye between a weakly buffered aqueous solution of about 1/100th normal buffer content and chloroform was determined at different pH values; at about $p\mathrm{H} = 8$ the dye is practically completely removed from the water by the chloroform.

The concentration of dye was determined by extraction with chloroform and measurement of the spectro-photometric extinction at the wavelength of maximum visible absorption, about 570 mμ. The dye solution of given pH was shaken with a silver bromide precipitate, the integral surface of which could be computed from the size-frequency curve of the particles. On plotting amount of dye carried down by the silver bromide against residual concentration of the dye in the solution, curves were obtained which first rose rapidly, then reached a period of practically equal adsorption, which was again followed by a period of almost vertical ascent. The interpretation of these results is as follows: The dye is at first adsorbed to the surface to the point of surface saturation of the silver halide with *dye* molecules. The dye disperses in water to *colloidal* as well as to true solution and the last ascending portion of the curve corresponds to the precipitation of the dye on the silver bromide, that is, to the *colloidal* or *mechanical* adsorption. The point at which the final ascending portion of the curve when produced cuts the concentration axis of the dye, represents the *true solubility* of the dye in the aqueous solution.

Of various adsorption formulæ, the so-called Freundlich formula failed entirely to represent the data, but a modification of Langmuir's formula for the monomolecular adsorption of gas molecules to a plane surface was found to fit the data very well.

From the known total area of the silver bromide, and the lattice interval, the number of ions in the surface layer can be calculated. Assuming octahedral surfaces, which all the evidence indicates, the adsorption density of the dye on the surface diminishes as the pH of the solution is decreased, but at a pH of 5·5 it was calculated that one molecule of dye was adsorbed for 20 ions of the lattice surface.

Several reasons might be advanced in explanation of the low adsorption density of the dye. From optical sensitising experiments it has been known for a long time that the effective amount of dye adsorbed was of a very low order. Mr. T. Thorne Baker has recently contended (*Phot. J.*, 50, 299, 1926) that the dye is only adsorbed to what have been termed the 'sensitivity specks' in the silver halide, which have been shown by the writer to be, in all probability, silver sulphide. This interpretation does not at present seem probable, in view of the existence of a similar order of adsorption of the dye when the silver halides are prepared in the absence of sulphiding material. It seems equally probable that the dye is actually held to the silver halide, that the dye molecule has a very large area, and very possibly tends to orient itself parallel to the lattice surface. The most obvious condition would be for the dye cation to be held to a bromide ion of the silver halide lattice, but residual affinity in other parts of the molecule may also be exerted.

The solubility of the dye in water is enormously diminished in the presence of quite small amounts of soluble halides, and the part which these play in the adsorption process is being investigated. These measurements must be carried out in a yellow light such as is given by Wratten Safelight 00, owing to the photochemical reactivity of the dye.

The work is to be extended, and it is hoped to publish a fuller account shortly.

The Genetics of Evening Primroses and Mice.

IN 1905, Dr. G. H. Shull, of Princeton, received from Dr. de Vries ten rosettes of *Oenothera lamarckiana* from the locality at Hilversum, Holland, which had supplied the original material for the classic researches of de Vries many years before. In 1921, among the descendants of these plants appeared a colour-mutation which Shull calls 'old gold' (*vetaurea*). The petals are flushed with apricot-colour, strong toward the base, fading out distally. In a very interesting and detailed paper (*Genetics*, May 1926, p. 201), Shull describes the behaviour of this mutant in a variety of crosses. It is recessive to the ordinary yellow flower. In order to test it further, Shull introduced into his cultures the very pale yellow mutant called 'sulphur' (*sulphurea*), and was surprised to find that old-gold was complementary to sulphur, the two when crossed giving invariably plants with flowers of the normal yellow colour. Accordingly the normal yellow is expressed by the symbol SSVV (double dominant), the homozygous sulphur by ssVV, and the homozygous old-gold by SSvv. By suitable crosses the double recessive ssvv was obtained, and proved to be a pale flower, with the bases of the petals flushed with the apricot tint. Shull called it 'gold-centre' (*aurata*). The amount of the reddish or old-gold colour is much less than in old gold.

From my experience in breeding sunflowers, and to a lesser extent evening primroses, I feel sure that microscopical and chemical investigations would make this case clearer. The normal yellow is due to plastids in the cells, and 'sulphur,' while possibly having paler plastids, more probably has them less numerous or diluted, with more air in the cells—an approach toward the condition of the white-flowered species. The old-gold effect must surely be due to an anthocyanin soluble in the sap. An inhibitor of this anthocyanin suffusion is dominant, and exists in the normal yellow flowers. Thus the allelomorphs are not really yellow and old gold, but no flush, and flush, yellow being present in either case. If the allelomorphs in the case of yellow and sulphur are dense and dilute, this explains why less anthocyanin is visible in the double recessive than in old gold, on the same principle as that of the white evening primroses, which turn pink on fading. It is possible that as much anthocyanin could be extracted from the one as the other.

In experimenting with transplantable neoplasms or tumors in mice (*Genetics*, May 1926, p. 294), Mr. Leonell C. Strong, of the Bussey Institution, found that transplants from a spontaneous cancer rarely grew well in the first generations, but usually the number of successful takes increases until a very high rate is attained. He directs attention to certain cases in which abrupt changes have taken place in the behaviour of the tumours, so that from one original type he now has four, with different reactions appropriate to each. He shows that these differences cannot possibly be ascribed to anything in the host mice, and so is driven to the conclusion that somatic mutations have occurred in certain of the tumour cells. The general improbability of the occurrence of such mutations in so short a time apparently cannot count against the observed facts. Possibly there may be a slightly different explanation. The complicated mitotic phenomena are of course controlled by genetic factors. If we assumed (and the idea is not new) that the original tumour cells arose as the result of a breakdown in or disturbance of the mitosis-controlling factor or factors, this one change would seem to account for all the rest. The partially inadequate control would result in sundry mitotic errors, and those which led to the most prolific and 'non-specific' tumours would be perpetuated in preference to others. T. D. A. COCKERELL.

Mathematical Proof *versus* Observation.

THE history of the physical sciences offers many examples of theories which have been 'proved' mathematically and been set as foundation-stones in the edifice of science, only long after and when a superstructure has been reared upon them to be abandoned as untenable. The operation of taking out a 'foundation stone of science' presents all the difficulties which are encountered in extracting its physical parallel.

Mathematical formulæ to be applied practically require the use of numerical factors which are often wanting or are subject to such wide range that a large element of guessing enters into the computation. In actual practice a far greater source of error is one which might well be eliminated—the neglect to compare and check carefully the results of the mathematical treatment with the facts of observation.

A noteworthy example of the abiding faith in mathematical formulæ when not in harmony with observation, is afforded by a formula in common use where the disparity between the calculated and the observed numerical values is that between 26,000 and 200. A neglected factor has just been discovered which brings the theoretical and the actual values in this case into harmony. Obviously this example might be cited to show the value of mathematical treatment; but even more clearly it sounds the warning against putting our faith in any mathematical treatment of physical phenomena where a careful comparison has not been made to see that the results of the computation check with the observations.

Even when the mathematician has himself been careful to state the limitations to which his conclusions are subject because of the assumptions made, those who cite him are not so easily controlled. As a striking example it is stated in a recent review: "Dr. Jeffreys has recently demonstrated (*Quart Jour. Roy. Met. Soc.*, vol. 52, p. 85, January 1926) that whatever superficial increase of pressure there may be over either pole or over Greenland, in consequence of the cold, this is a shallow surface effect, and that both poles are seats of low pressure"; as though such a fact could be proved by mathematical discussion alone. When we consult the original, we find that this eminent mathematician has stated that his discussion has not been developed for the actual earth on which we live; but for a hypothetical earth on which the atmospheric circulation is assumed to be symmetrically disposed with reference to the geographical poles, operates without friction, and is without interference from the irregular distribution of land areas. No one of the assumptions holds true of our earth.

It should be stated that Dr. Jeffreys has faithfully tried to compare his conclusions with observation, though without very happy results; for neither Greenland nor the north and south polar areas are regions of low atmospheric pressure. The north polar area is one of nearly normal atmospheric pressure, whereas the south polar region and Greenland are both notably areas of high atmospheric pressure. Observations are consistent in support of these statements. WM. H. HOBBS.

Ann Arbor, Michigan, October 28.

The Oscillations of Superposed Fluids.

THE explanation of Franklin's experiment quoted in NATURE of December 4, p. 823, is purely dynamical. When a stratum of oil rests on water the restoring forces of gravity called into play by any disturbance of the interface are comparatively small, owing to the slight difference of density. Free oscillations are consequently slow, and so in Franklin's case apparently came within the range of the imposed periods due to the motion of the ship.

The formula for the periods ($2\pi/\sigma$) of waves of given length ($2\pi/k$) in the case of two superposed liquids of depths h, h' and densities ρ, ρ' was given long ago by Stokes. The equation has two roots, which reduce to

$$\sigma^2 = gk \tanh k(h+h'), \quad \sigma^2 = gk\frac{\rho-\rho'}{\rho}\,\frac{\sinh kh \sinh kh'}{\sinh k(h+h')},$$

approximately, when the ratio $(\rho-\rho')/\rho$ is small. The former root corresponds to the motion of the fluid mass as a whole, as if it were of uniform density throughout. The second root is relevant to the observed phenomenon, the disturbance being confined to the neighbourhood of the interface. The ratio of the amplitudes at the upper and lower surfaces is in fact

$$-\frac{\rho-\rho'}{\rho}\cdot\frac{\sinh kh}{\sinh k(h+h')},$$

approximately. If the fluids are contained in a cylindrical vessel of radius a the admissible values of k are given by the roots of $J_n'(ka)=0$. The slowest oscillation of all corresponds to the smallest root of this in the case of $n=1$, namely, $ka=1{\cdot}841$. The interface then oscillates about a nodal diameter.

For a numerical example, probably not very different from the circumstances of Franklin's case, we may assume $h=h'=4$ cm., $a=4$ cm., $(\rho-\rho')/\rho=0{\cdot}9$. With the above value of ka this gives a period of 1·36 sec. The corresponding ratio of the amplitude at the upper surface to that of the interface is only 0·0155, or less than one-sixtieth. If the oil were removed the period would be 0·302 sec. H. LAMB.

6 Selwyn Gardens, Cambridge.

Rainfall Interception by Plants.

THE major part of the 'interception gain' found by Mr. Phillips in his experiments at Deepwalls, described in NATURE of Dec. 11, p. 837, is no doubt due to the screen catching rain which would otherwise have fallen on the lee side of the gauge. This would become negligible if a large area were covered by a comparatively close network of screens, except for a narrow strip at the edge of the area, where the gain would still be appreciable. This particular experiment does not appear likely to give information about the amount of water deposited on plants when there is no rain (or practically no rain) falling to the ground.

The percentage excess in Mr. Phillips' experiment should be greatest when the ratio of the velocity of the wind to the rate of fall of the raindrops is greatest.

E. GOLD.

Allotropy.

By Prof. A. Smits, University of Amsterdam.

THE liquid state of aggregation or phase of an element under its own vapour pressure is always stable over a certain temperature range, that is to say, from the critical point to the solidifying or melting-point. Below this point the liquid is not stable, for in this case it has gone beyond its range and should have crystallised, but seems to be too indolent or has forgotten to do it.

All liquids can be cooled more or less below the solidifying point without freezing, or, in other words, can be supercooled. This supercooled state is metastable, since although it is not stable it can be realised. But what about the crystallised aggregation? If only *one* solid state exists the case is very simple, for then we can say, from the solidifying point to lower temperatures the solid state is stable. It is generally found, however, that the same element can exist in two or more crystalline states, or modifications, differing in physical and chemical properties. This phenomenon is called *allotropy*, or better *phase-allotropy*, as the intention is to indicate the appearance of two or more similar *phases*. If at any time two liquid states of an element are found, one may also speak of phase-allotropy. It should be observed that though we have referred here to elements, the same holds for compounds, if the different phases have the same composition.

Two cases must now be distinguished. It is possible that what is said above holds only for one of the solid states, whilst the other modifications are always metastable. This phenomenon is called *monotropy*. The peculiarity of such metastable states is, that contact with the stable state or with a solution, etc., can effect the transformation into the stable state. When such a metastable state can be heated to the melting-point, then it appears that the melting temperature is lower than that of the stable state. Sometimes these melting-points are very close and sometimes they are a great way apart. For example, the stable violet phosphorus melts at 589·5° C., whilst the metastable black modification melts at 588°, and the metastable white modification at 44·1°. It appears also that the stability is transferred from one modification to the other. For example, over a certain temperature range *A* is stable and *B* metastable, and above a given temperature the position is reversed; *B* becomes stable and *A* metastable, and at this given temperature both of the two modifications can exist stable, side by side, and be in equilibrium. This temperature is called the transition temperature and is completely comparable with the melting temperature, at which the solid and the liquid aggregation are in equilibrium. This phenomenon is called *enantiotropy*. A good example is mercury iodide: below 127° the red tetragonal modification is stable and above this temperature the yellow rhombic modification is the stable one. At 127°, the transition temperature, both forms are stable. It must be remembered here that we have considered liquid and solid phases, being under vapour pressure. It is necessary to mention here that it happens frequently, that whilst under vapour pressure only one crystalline phase is stable; under higher pressures the transition phenomenon occurs.

Though, consequently, two modifications only can be stable, side by side, at the transition temperature, it happens frequently, owing to retardation, that a stable and a metastable modification exist side by side over a large range of temperature. In this case, consequently, the substance is a *conglomerate* of two modifications, one only of which is stable. This behaviour, as it is only a consequence of retardation phenomena, might have been expected, and has no connexion at all with those to be described below.

Until fifteen years ago it was considered that the so-called single substances were completely understood, and that no new aspects remained for investigation. The connexion between the different aggregations of a single substance was indicated simply by a diagram on which the vapour pressure curves and melting-point curves were drawn, or in other words, by indicating how the vapour pressure changes with temperature and how the melting-point changes with pressure. Such a diagram shows that the vapour pressure of the liquid or of the solid state, at a certain temperature, has a constant value, and the same holds for the melting-point at a definite pressure. As, however, in some cases it was found that the vapour pressure could be changed without altering the temperature, and that the melting-point could be altered without changing the pressure, and that in certain cases the transition temperature could be shifted, it was clear that something was lacking in our knowledge of the states of aggregation.

Some of these phenomena to which I refer are described below. It was found that by partial distillation of most carefully purified crystalline violet phosphorus at 360°, a residue was obtained showing a much lower vapour pressure than the original substance. The original violet phosphorus at 460° had a vapour pressure of 3 atmospheres, whilst the vapour pressure of the residue at the same temperature was 1 atmosphere (*Zeitsch. f. phys. chem.*, 91, 249, 1916; "The Theory of Allotropy," p. 214). Further, it was found that the melting-point of violet phosphorus was considerably lower when the substance was slowly heated, than that observed when the heating was carried out quickly. The maximum difference observed was about 20°, and the melting did not take place at a constant temperature, but over a range of temperature (*Zeitsch. f. phys. chem.*, 91, 249, 1916; "The Theory of Allotropy," p. 195).

In the same way, according to the previous history of the substance, the fat trilaurine could be caused to melt, arbitrarily, at any temperature between 18° and 46°. Rhombic sulphur showed similar results, but on a small scale. As regards the transition phenomenon mentioned above, it was found that according to the rate of cooling the transition temperature of mercury iodide could be raised some degrees ("The Theory of Allotropy," pp. 188, 193, 201, 206), and the same holds for the transformation of β-crystobalite into α-crystobalite, where the effect is more marked. Two crystalline modifications of silica prepared at 1600° showed that the transformation $\beta \rightarrow \alpha$ had already taken place about 18° above the temperature at which the change in material prepared at 1000° occurs.

It is evident that a change of the vapour-pressure of the liquid state causes a change in the boiling-point; consequently a change of the boiling-point indicates that the vapour-pressure of the liquid is altered. A change of the vapour-pressure of the liquid causes also a change of the melting-point, unless the new vapour tension of the solid state has accidentally such a value that the new vapour tension lines of liquid and solid meet at the ordinary melting temperature.

As regards changes of the boiling-point, most interesting results were obtained by H. B. Baker and Mrs. Baker (*Trans. Chem. Soc.*, 51, 2339, 1912). They found that while pure, not intensively dried nitrogen trioxide boils under atmospheric pressure at $-2°$, the intensely dried liquid, freed from the last traces of water by phosphorus pentoxide, boiled at $+43°$, that is, 45° higher. With nitrogen tetroxide they obtained a similar result, the boiling-point of the intensely dried liquid having risen more than 47°.

These investigations were the beginning of a series of still more important experiments, carried out by Baker (*Trans. Chem. Soc.*, 121, 568, 1922) on the intensive drying of ten liquids and some solid substances of very different character. The examination of these substances, being postponed by the War much longer than was intended, was delayed eight or nine years. The result was that all the liquids showed a great rise of boiling-point. For example, the boiling-point of benzene had risen from 80° to 109°, that of ethyl alcohol from 78·5° to 138°, that of ethyl ether from 35° to 83°, that of hexane from 68·4° to 82°, that of bromine from 63° to 118°, and that of mercury from 358° to 420°.

Further, it was found that if these intensively dried liquids were allowed to take up a trace of water-vapour, for which purpose contact with ordinary dried air (air which had been passed first through concentrated sulphuric acid and then over phosphorus pentoxide) was sufficient, the liquids regained their original state with the normal boiling-points. In some cases, as with alcohol, the normal state was reached in twenty-four hours, but with benzene it required a month.

At first sight it might be thought that this phenomenon is a simple superheating of the liquid. Indeed it is well known that if a liquid and the wall of the vessel containing the liquid are freed from gases, it is possible to heat the liquid some degrees above the normal boiling-point before boiling occurs. Now if intensive drying facilitates this phenomenon, Baker's results might be described to superheating. For those who are not familiar with the phenomenon of superheating, it may be mentioned that should anyone succeed in heating water in an open vessel, for example, up to 130°, it would be most necessary for the experimenter to place it under cover, since that at any moment an intense and explosive boiling might take place (explosion of boilers). Taking now into consideration the fact that boiling-points up to 60° above the normal boiling-points were observed by Baker and that the boiling took place very quietly, then it is clear that considerable superheating was altogether out of the question. Corresponding to this, Baker found that at the same temperature intensively dried ether showed a lower vapour-pressure than the moist liquid. The vapour-pressure is a quantity which can be accurately measured, and since a decrease of vapour-pressure corresponds to a rise of the boiling-point, it was proved that the phenomenon observed by Baker was the result of a change of the state of the substance involving a change of the vapour-pressure. That the state of the substance is really changed by intensive drying followed from the results obtained by determining the mean size of the molecules in the intensively dried liquids, for which values were found 2 to 2·5 times as large as in the moist liquids. Consequently, association or polymerisation had taken place.

These results, being completely unsuspected and lying far beyond the horizon of current conceptions, were at the time not generally accepted. It was not possible to say how Baker could have erred, but one could simply not believe that the properties of a substance could change so much.

Though chemists and physicists in general were sceptical, in the chemical laboratory of the University of Amsterdam the results obtained by Baker were received with great enthusiasm, since there in 1911 a theory had been put forward by means of which such results could be easily explained. Baker's results were, indeed, a valuable confirmation of the new theory ("The Theory of Allotropy," 1922).

This theory assumes that every state of aggregation, even of the most simple substance, in reality is complex, that is to say, it is built up of molecules of different kinds. Taking, for example, benzene, it is assumed that in each state of aggregation, namely, gaseous, liquid, and solid, it consists of different kinds of molecules. For simplicity only two different kinds of molecules are assumed, indicated by the indices α and β, thus $C_6H_6\alpha$ and $C_6H_6\beta$. In general, we cannot say beforehand in what way these kinds of molecules will differ. First, it is possible that these molecules are equal in size but different in structure, and these differences may be very small. Secondly, the molecules may be of different size. With benzene it is probable that the different kinds of molecules differ in size, and for simplicity we shall assume here that one kind is a simple molecule, C_6H_6, and the other kind is an associated molecule $(C_6H_6)n$, formed by combination of n simple molecules to form a new large molecule. Let us consider now pure benzene. This liquid boils at 80°. Supposing we had a liquid consisting only of simple molecules C_6H_6, then this liquid would be more volatile, would have a higher vapour-pressure and a lower boiling-point than ordinary benzene, let us say 70°. If we had, on the other hand, a liquid containing only the larger molecules $(C_6H_6)n$, this liquid would be much less volatile, and would have a much higher boiling temperature, let us say 150°. Ordinary benzene boils at 80°, since in this liquid, molecules of the liquid boiling at 70° and molecules of the liquid boiling at 150° are present side by side.

It is natural then to ask: Is benzene a mixture? Certainly it is, for that is exactly what these considerations indicate. Benzene vapour and benzene liquid are gaseous and liquid mixtures, and crystallised benzene, that is to say, every crystal of the solid state, is also a mixture, namely, a mixed crystal, but, as we shall see, they are not ordinary mixtures.

By adding water to alcohol we obtain an ordinary mixture, and the properties of that mixture depend on the proportion in which the substances are mixed. A certain mixture begins to boil at a definite temperature, begins to solidify at a definite temperature, and shows a definite vapour-pressure at a certain temperature. The property by which a liquid is known as a mixture is this, that by distilling off a portion, or by solidifying a part, we obtain a liquid of different composition and therefore different boiling-point, different vapour-pressure, and different solidifying point. The easiest manipulation is partial distillation. Applying this method, for example, to a mixture of equal quantities of water and alcohol, then a vapour escapes which is richer in alcohol than the liquid, and the remaining liquid has become poorer in alcohol, effecting a decrease of the vapour tension and an increase of the boiling-point.

This decrease of the vapour-pressure and increase of the boiling-point by partial distillation is a characteristic property of a mixture. If a solidifying mixture gives mixed crystals—*i.e.* crystals in which all the substances we have mixed are present, just as every drop of a liquid mixture contains each part present (a mixture of chlorine and bromine is a very good example)—then for these mixed crystals this rule holds just as for liquid mixtures, namely, by partial distillation the vapour tension is decreased.

It is mentioned above, however, that pure benzene is a mixture. Yet if benzene is submitted to partial distillation the properties of the liquid are not changed at all. Vapour-pressure, boiling-point, melting-point are exactly the same as before. What is, then, the explanation of this behaviour, which is characteristic of a true simple substance, whilst benzene is not simple? It seems indeed a contradiction, but it is not so. Although benzene is composed of different kinds of molecules, it behaves as a single substance, on account of the great velocity with which these kinds of molecules are transformed in each other. These mutual transformations are indicated in the following way:

$$nC_6H_6 \rightleftarrows (C_6H_6)n.$$

These two very rapid opposite reactions lead to a so-called equilibrium, in which the proportion between the single and the associated molecules, or the composition, has a definite value at constant temperature and pressure. If we have to do with ordinary dried benzene, we have no means of changing this composition, temperature and pressure remaining constant. Let us assume we had an instrument which enabled us, just as a stork catching fish from the water, to catch up and carry off the large molecules in liquid benzene. Still we should not succeed in making the remaining liquid poorer in big molecules, for so soon as the number of large molecules is decreased the small molecules will be associated to form large molecules, until that proportion between small and large molecules is reached which corresponds with the inner equilibrium.

By distilling benzene as rapidly as possible a similar process occurs; the smaller molecules are more rapid than the large ones, and in consequence of this the smaller molecules will leave the liquid surface in greater numbers per second than the large molecules. Notwithstanding this the liquid does not get poorer in small molecules, since the larger molecules dissociate until the proportion of the different kinds of molecules, corresponding with the inner equilibrium, is reached.

According to these considerations, a so-called simple substance is in reality a mixture, not an ordinary one, but a mixture with an inner equilibrium. Now it is evident that if we were able, for example, in the case of benzene to withdraw the big molecules with a velocity greater than the velocity with which they are formed again, the properties of benzene would change. But in most substances these inner transformations are so rapid that an artificial change of the composition is impossible.

We can say, consequently, that it is the rapid establishment of the equilibrium between the different kinds of molecules of the same substance (inner equilibrium) which makes a substance such as ordinary pure benzene, behave as a true single substance.

Considering the results of Baker's experiments from this point of view, it is not difficult to give an explanation of them. Only one very probable supposition is to be made, namely, that the process of intensive drying effects a decrease of the velocity of the transformation between the different kinds of molecules, and that finally the transformation is stopped completely.

In benzene, not intensively dried, the two opposite rapid transformations,

$$nC_6H_6 \rightleftarrows (C_6H_6)n$$

are taking place, but in intensely dried benzene these transformations take place no longer, and the arrows have no longer any signification; the two kinds of molecules have become strangers to each other; *i.e.* intensively dried benzene has become an ordinary mixture.

What can we say now of this mixture? We have already mentioned above that a liquid consisting exclusively of the small simple molecules, C_6H_6, would be more volatile and would boil perhaps at 70°, whilst a liquid containing only the big, associated, molecules $(C_6H_6)n$ would be much less volatile and would boil perhaps at 150°. From this it follows that when, by intensive drying, benzene has become an ordinary mixture, it is a mixture of two substances differing greatly in volatility. Heating this mixture in an open vessel, then, as in most cases, principally the more volatile part will escape, by which the remaining liquid becomes richer in the less volatile part, and when the boiling-point is reached the liquid, considerably enriched in the less volatile and higher boiling part, will begin to boil at a temperature higher than the boiling-point of moist benzene.

This explanation has been tested and confirmed (*Jour. Chem. Soc.*, 125, 1068, 1924), but in addition another supposition has been confirmed, namely, that the process of intensive drying effects more or less a change in the proportion between the different kinds of molecules at the drying temperature; *i.e.* it effects a change of the inner equilibrium (*Jour. Chem. Soc.*, 128, 2655 and 2657, 1926). It seems that with the progress of the drying process the molecular proportion mentioned above changes gradually more or less; this is accom-

GRIFFIN
AND
BAIRD & TATLOCK

At the Science Masters' Association Exhibition in Oxford, instruments for the School Laboratory will be shown, including many of the new models developed recently in our Experimental Departments and described in Catalogue (No. 50) recently published.

PHYSICAL SOCIETY EXHIBITION

SCIENCE MASTERS' ASSOCIATION EXHIBITION

At the Physical Society Exhibition in London, Griffin and Baird & Tatlock will exhibit new experimental apparatus, which will include the Boys Recording Gas Calorimeter, Microid Pyrometers, and new models of Penetrometer, CO_2 Indicator and Oil Testing Machines.

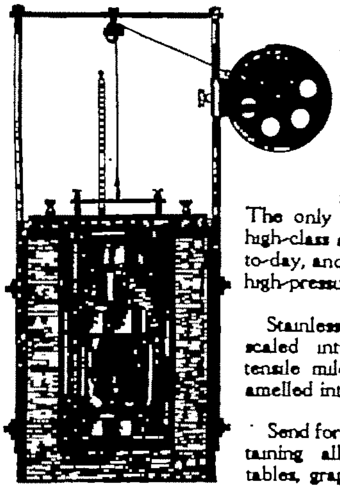
THE
MAHLER-COOK BOMB CALORIMETER



For determining the calorific value of Fuels (Coal, Coke, Oils, etc.)

The original Bomb Calorimeter, used all over the World and first introduced by the present makers in 1900. The only reliable, accurate, and high-class apparatus on the market to-day, and made by Engineers and high-pressure experts.

Stainless steel Bombs with descaled internal finish, or high tensile mild steel Bombs with enamelled interior.

Send for Illustrated Booklet containing all working instructions, tables, graphs, etc.

High Pressure Apparatus, Centrifuges, Microtomes, Electroscopes, Steam Meters, Electric Furnaces, etc.

BROOKLYN BOTANIC GARDEN MEMOIRS

Volume I : 33 contributions by various authors on Genetics, Pathology, Mycology, Physiology, Ecology, Plant Geography, and Systematic Botany. Price, $3.50 plus postage.
Volume II. : The Vegetation of Long Island. Part I. The Vegetation of Montauk, etc. Pub. 1923. 108 pp. Price, $1.

AMERICAN JOURNAL OF BOTANY

Devoted to All Branches of Botanical Science.

Established 1914. Monthly, except August and September. Official publication of the Botanical Society of America.
Subscription, $7 a year for complete volumes only. Volumes 1-13 complete, $106, post free. Single numbers, $1 each, post free. Prices of odd volumes on request. Foreign postage, 40 cents.

ECOLOGY

Devoted to All Forms of Life in Relation to Environment.

Established 1920. Quarterly.
Official publication of the Ecological Society of America. Subscription, $4 a year for complete volumes only. Back volumes, 1, 2, and 4-7, $5 each, post free. Single numbers, $1.25, post free. Foreign postage, 20 cents.

GENETICS

A Periodical Record of Investigations in Heredity and Variation.

Established 1916. Bi-monthly
Subscription, $6 a year for complete volumes only. Single numbers, $1.25, post free. Back volumes, 2-10, $7 each. Foreign postage, 50 cents.

Orders should be placed with

POCKET
CALCULATOR

"accuracy is about four times that of the ordinary ten-inch slide rule . . ."

writes a B.Sc., from Canada. This unsolicited letter goes on to state : "My estimate is that I have made about fifty thousand calculations with your product. About twenty-two thousand hydraulic calculations have been made in the last month with a probable error of any one calculation not greater than 5/100 of 1%."

Otis King Model K for multiplication, division, proportion, percentages. Model L gives, in addition, all powers and roots—fractional or otherwise—of all numbers without limit.

Price, packed in leather case, 21/- (special Black Cursor 1/6 extra), post free within U.K.

Write for illustrated and fully descriptive folder.

CARBIC LIMITED

FROM A REVIEW IN NATURE

"This volume represents the mature thought of an accomplished ichthyologist and traveller who speaks from the point of view of a naturalist and field observer and marshals, in the first nine chapters, all the difficulties that have arisen through field observation in the original concept of Darwinism. . . . A thoughtful and, in large part, original contribution to the newer modern aspect of the evolution theory."—*Oct.* 30, 1926.

GAS SUPPLIES FOR LABORATORIES.

Mansfield Oil-Gas apparatus places in the hands of scientists whose laboratories are not supplied with town's gas, a means of securing a supply of gas which gives a perfect oxidising or reducing flame.

This plant has been supplied during the past 50 years to many of the important laboratories in the British Empire.

Write for particulars to
MANSFIELD & SONS, LTD.,

panied by a decrease of the velocity of the two opposite transformations, until finally *they are stopped completely*. Now it will be clear that the theory is also capable of explaining the phenomenon noted already in the solid state of some substances, for the theory states that every state of aggregation, consequently also the crystalline state of a so-called single substance, is built up of different kinds of molecules. The crystalline state of a single substance is consequently a mixed crystal, not an ordinary one, but a mixed crystal in inner equilibrium.

As I have observed already, the velocity with which the inner equilibrium between the different kinds of molecules is established in the different states of aggregation, seems to be a very characteristic property of substances, so that we can speak of rapid and slow substances. Rapid substances can undergo rapid changes without coming out of inner equilibrium, but slow ones can be disturbed. In the light of these new considerations, the results obtained with violet phosphorus can be explained easily. Violet phosphorus is a slow crystalline substance; it is a slow mixed crystal, and therefore evaporation at relatively low temperatures will cause the remaining mixed crystal to become poorer in the most volatile molecular species, thereby decreasing its vapour tension.

Another phenomenon, mentioned already, showing that the melting-point and transition-point depend on the previous history, can also be predicted by the theory. If the pressure is kept constant and the temperature is changed, it will of course depend on the velocity with which inner equilibrium is established and the rate of change of the temperature, whether for practical purpose inner equilibrium always exists. If the temperature changes so rapidly that the inner equilibrium cannot adjust itself to it, inner equilibrium is not realised, but disturbed conditions are obtained, which are naturally metastable, and the properties of these states, such as specific gravity, solubility, transition-point, melting-point, boiling-point, etc., will deviate from those of the inner equilibrium state. In connexion with this it is clear that it is very difficult or impossible to show complexity with rapid substances. It is easily understood, therefore, that complexity is apparent only in rather slow substances, and as most substances are rapid, the complexity was only proved in a relative small number of cases.

It will be evident now how valuable it is to have a means by which it is possible to change a rapid substance into a slow substance, and finally to bring all inner molecular transformations to rest. A substance to which this has been applied with great success is sulphur trioxide (*Jour. Chem. Soc.*, 125, 2554, 1924; 128, 1108, 1603, 1926). The intensely dried crystalline state has been studied in detail and the phenomenon already found with violet phosphorus was observed here in a marked degree. It was found that sulphur trioxide, dried for one month or longer in a certain way with freshly distilled, purest, very fine phosphorus pentoxide, becomes so exceedingly slow that it behaves distinctly as a mixture. Since the range of temperature and pressure within which that behaviour reveals itself is much more easily approached than in the case of phosphorus, it could be studied more closely. Thus we could obtain by partial distillation substances of nearly every lower vapour-pressure and, within wide limits, of varying melting-points. The vapour-pressure could at ·50° be reduced to 1/15 of its normal value, whilst the melting-point could be raised from 62° to 95°, an increase of no less than 33°. The melting process in such a crystalline state, which has been much changed by partial distillation, is rather dangerous, since in the liquid formed, notwithstanding the intensive drying, in consequence of the higher temperature, inner transformations take place very rapidly. This causes a rapid increase of vapour-pressure, so that the chances are that the apparatus will burst.

The influence of X-rays on such markedly changed crystalline states is also noteworthy. We found that X-rays affect not only the establishment of the inner equilibrium, but also the transformation of the metastable forms into the stable modifications. I have referred here to the phenomena, observed with phosphorus and sulphur trioxide, but recently we have found analogous phenomena with a number of other substances such as phosphorus pentoxide, nitrogen tetroxide, hexane, benzene, etc.

All these phenomena show the complexity of the so-called simple substances, and we may expect that other substances in the intensely dried state will also show complexity, for there is little doubt that complexity is a general phenomenon. Whilst the old ideas of allotropy are completely powerless to explain these phenomena, they give strong confirmation to the principles on which the theory of allotropy is built, while the new phenomena can be explained completely by this theory. The new theory of allotropy shows among other things that in the most simple case the vapour-pressure lines and the melting-point line of a so-called single substance belong to a pressure-temperature-composition model in three dimensions, in which the two different kinds of molecules are the components. These lines take up a particular place in this space model, since they indicate the phases which are in inner equilibrium. But the whole space model refers to the field of the so-called single substance. When the substance is indeed completely dry and inner transformations are stopped, the whole domain of the substance can be studied. So long, however, as the intensive drying is not complete and the inner transformations are only strongly retarded, the same space model shows which phenomena may be expected. As to the different kinds of molecules, I have pointed out that the reason for the existence of these different kinds of molecules must probably often be sought in the existence of different kinds of atoms (*Ber. Sächs. Akad. Leipzig*, 75, 58, 1923), and in connexion with this it is interesting that recently, from the side of physicists, the same assumption has been made on quite different grounds (de Haas, *Kon. Akad. Amsterdam*, 1926).

Finally, to prevent confusion it is necessary to direct attention to the following points. Recently, papers have been published referring to experiments on the influence of 'traces' of water on different properties of substances, as for example solubility, etc. It will be sufficient to state here that these experiments deal with substances containing 'traces' of water *many thousand times* larger than in our cases of intensive drying and are consequently in quite a different field.

From the preceding considerations it follows that whilst for several years the so-called single substances were considered to have been completely investigated, and it was believed that new points of view could only be obtained by the study of more complicated systems, the close study of these single substances has recently become extremely interesting. From the new point of view already reached, the phenomenon of allotropy with all the various phenomena associated with it and the influence of intensive drying can be surveyed.

In conclusion, one among several interesting questions may be put forward here. Consider for a moment a substance such as benzene, which has become an ordinary mixture by intensive dryings. Benzene is one among the large number of substances for which, after drying in the ordinary way, various physical constants, such as critical-point, melting-point, vapour-tension, specific weight, etc., are determined. Now it cannot be said that these constants have no value; on the contrary, they are very valuable, but they are not physical constants of the pure substance but of impure benzene, contaminated by an extremely small trace of water. Before the phenomena to which I have referred above were known, one would have attached little value to this observation, and one would have answered that such an extremely small contamination canno have any perceptible influence and can therefore be neglected. This is quite true, speaking of contamination in general, but now we know that water is a very special contamination, for on removing it completely, benzene becomes an ordinary mixture and our physical constants are no longer suitable. Thus the new theory opens up another field for investigations on which many generations of scientific workers may carry out important research. In future the so-called single substances will be really purified, which means they will also be dried intensively. From the mixtures obtained in this way the components will be separated and studied carefully. Thus the components of a so-called simple substance will be discovered, and no doub will often cause great surprise, since big and noteworthy differences may exist between the different kinds o molecules.

Sea-birds: Their Relation to the Fisheries and Agriculture.

By Dr. Walter E. Collinge.

Under the above title in Nature of April 8, 1920 (pp. 172-173), I gave a brief résumé of an investigation on the economic status of the commoner species of sea-birds of Great Britain then being carried out under the auspices of the Carnegie Trust for the Universities of Scotland. In that investigation, large series of each species from various localities during each month of the year were examined, and the food content of the stomach was estimated by the volumetric method. The investigation has now been completed, and a final résumé of the more important results may not be without interest. In all, nineteen species were examined, embracing 2309 specimens.

One of the most striking facts shown by this work is the very small percentage of fish consumed by the common gull, the herring gull, the black-headed gull, the common tern, the little auk, and the puffin. Hitherto, it has been generally assumed that all sea-birds feed upon fish, and that this item of their diet constituted the bulk, but such is far from the case. Of the total bulk of food consumed in a year, fish constitutes only 5·16 per cent. in the common gull, 18·20 per cent. in the herring gull, 3·73 per cent. in the black-headed gull, 18·01 per cent. in the common tern, 1·17 per cent. in the little auk, and 22·22 per cent. in the puffin. In the first three species, much of this small percentage of fish is obtained from shore refuse.

The case of the black-headed gull is most striking and significant. As a destroyer of injurious insects it is a most valuable bird, 24·70 per cent. of its food being of this nature, which is more than that consumed by either the rook or the blackbird. It also takes 4·38 per cent. of neutral insects and 0·19 per cent. of beneficial ones. The nature of the insect food is of considerable interest, both on account of the enormous amount that is consumed, and the particular species. Of these latter, it must here suffice to state that upwards of sixty different species were identified.

Respecting the bulk of food, accepting Newstead's computation that each bird feeding upon crane-flies will consume some 4000 per day or 28,000 per week the total quantity destroyed must be enormous. On the Fifeshire coast we have estimated in passing from field to field that at least 5000 birds were present on the land ten miles south of St. Andrews. Such flocks would consume 140,000,000 insects in a week. This however, is only on a small area. All along the coast and farther inland the same thing is taking place, so that the amount of insect life consumed must be prodigious. Moreover, it must be borne in mind that the percentage of cereals destroyed by this species is only 0·37 per cent. A similar striking record can be shown for the other five species mentioned.

Of the fish consumed, 27 species were identified The highest percentage consumed of any one species was 9 per cent. in the case of the greater sand eel 8 per cent. of the lesser sand eel, 6·5 per cent. of the gurnard, and 6 per cent. each of cod and herring haddock follows with 5·5 per cent., and then gunne and sprat each 3·5 per cent.; of flat fishes (all species) only 2·5 per cent. was present. Practically the whole of the food of the cormorant, shag, gannet, goosander red-breasted merganser, and great skua consists of fish, whilst 50 per cent. of the same item forms the food of the guillemot and the black-throated and great northern divers.

The bulk of the fish-food consumed by the nineteen species of birds investigated consists of species that are exceedingly common and also plentiful. There is no scarcity of these fishes, and were they still more plentiful they would in all probability only form additional food for predaceous fishes, and thereby add to the increase of a factor over which man has little or no control.

Of the 2309 stomachs examined, 422 were empty or nearly so. It would seem that if there is any scarcity or lack of food, the female bird is the one to suffer for of 97 partly filled stomachs of the herring gull

70 per cent. were of female birds and 30 per cent. males; whilst of 68 empty stomachs 60 per cent. were of females and 40 per cent. males. Of 123 partly filled stomachs of the black-headed gull 73 per cent. were of female birds and 27 per cent. of male birds, and of 82 empty stomachs 65 per cent. were of females and 35 per cent. of males. Only 16 guillemots were obtained with empty stomachs, and here again 75 per cent. were of female birds and 25 per cent. male. Of the remaining empty or partly filled stomachs of eleven species, namely, thirty-six in all, 62 per cent. were of female birds and 38 per cent. of males.

The range of variation of the food according to locality is interesting. Of the 539 herring gulls examined, 351 were obtained on the coast, or nearby, and 188 were obtained from agricultural districts. In the former, food fishes constituted 13 per cent. of the total food consumed, other fishes 4·7 per cent., and injurious insects 14·1 per cent. Those from agricultural districts gave the figures 9·2 per cent. of food fishes, 7·2 per cent. of other fishes, and 12·5 per cent. of injurious insects, showing that the diet of this species gives only a small range of variation. With the black-headed gull the figures are more striking. Those from the coast show 11·5 per cent. of food fishes, 8·3 per cent. of other fishes, and 24 per cent. of injurious insects. From agricultural areas the percentage of food fishes is only 4, other fishes 2, and injurious insects 32·7.

In all the gulls, annelids, crustaceans, molluscans, echinoderms, etc., figure largely, and in nearly all cases a considerable percentage of this is obtained from shore refuse. In the common gull the percentage is 60·69, the herring gull 48·36, the lesser black-backed gull 39·75, and the black-headed gull 44·04.

For the first time we have a volumetric analysis of the food of the common tern, and the results are all in this bird's favour. The whole of the food is of an animal nature, and 53·70 consists of fish. Of this item 18 per cent. is made up of food-fishes and 35·70 per cent. of non food-fishes. Summarising the figures for the total food content, it is shown that 81·99 per cent. of the food is of a neutral nature, and (if we regard the food-fishes eaten as an injury) 18·01 per cent. injurious. It is very significant that no traces of fresh-water or flat fishes were met with.

As a result of this investigation, and the expression of opinion of those who have devoted a lifetime to fisheries investigation, we are of opinion that no action of sea-birds can produce any appreciable effect upon the plenitude of the fishes of the sea. Moreover, many of the species of birds are exceedingly valuable from an agricultural viewpoint, and their wholesale destruction may be fraught with the gravest possibilities.

Obituary.

Prof. C. J. Eberth.

Prof. Carl Josef Eberth, whose death occurred in Berlin at the beginning of December, was born in 1835 and completed his ninety-first year last September. His earlier work was carried out in Zürich, but for many years he held the post of professor of pathological anatomy in the University of Halle. Zoology, anatomy, histology, pathological anatomy, and bacteriology were all enriched by his researches, and his published papers include investigations on nematode worms, fœtal rickets, the structure and development of blood capillaries, thrombosis, the histology of the lung and liver, mitosis, and on inflammation.

Eberth's name is probably best known in connexion with the discovery of the bacillus of typhoid fever. In 1880 and 1881 he published papers in Virchow's *Archiv* describing a bacillus which he found present in the spleen and mesenteric glands of cases of typhoid fever. The bacilli occurred in scattered groups, and were not distributed generally in the tissues, and appeared to be characteristic and distinct from other organisms which were occasionally seen. Of 40 cases of typhoid fever investigated, this bacillus was found in 18 only; it was also absent from 24 cases of tuberculosis and other diseases. Koch, about the same time, also noted the presence of a similar bacillus in typhoid cases and published photo-micrographs of it. Gaffky, in 1884, confirmed Eberth's observations, finding the bacillus in 26 out of 28 cases of typhoid fever investigated, and isolated and cultivated the organism, which since has sometimes been known as the Eberth, or Eberth-Gaffky, bacillus.

Prof. Eberth, who had lived in retirement for many years, was created a "Geheimrath," and a *Festschrift*, with excellent portrait, was dedicated to him on the occasion of his ninetieth birthday last year (*Beiträge zur path. Anat.* Bd. 74, 1925).

R. T. Hewlett.

Mr. Leslie D. Currie, palæontologist on the staff of the Burmah Oil Company, was drowned while bathing in Burmah on November 9. Mr. Currie had only three weeks before arrived in the country, after a brilliant career in the University of Glasgow, during which he had done some promising research work on some undescribed Silurian Crustacea. His death, at the age of twenty-two years, removes a palæontologist of great promise.

We regret to announce the following deaths:

Dr. Walther Bremer, Keeper of the Irish Antiquities in the National Museum, Dublin, whose archæological work included the identification of Asturian flints at Island Magee.

Dr. Franz Exner, emeritus professor of physics in the University of Vienna and a member of the Vienna Academy of Sciences, on November 15, aged seventy-seven years.

Dr. James F Kemp, professor of geology since 1891 in Columbia University, distinguished for his work in economic geology, on November 17, aged sixty-seven years.

Dr. C L. Withycombe, formerly of the Imperial College of Tropical Agriculture, Trinidad, and recently appointed lecturer in advanced and economic entomology in the University of Cambridge, on December 5, aged twenty-eight years.

News and Views.

The congratulatory dinner given at Cambridge on Saturday last to Sir J. J. Thomson, Master of Trinity, will long be cherished in the memory by all who were privileged to take part in it. The occasion was Sir Joseph's seventieth birthday, and the celebration was arranged by the Cavendish Society, which consists of past and present students of the Cavendish Laboratory, together with members of the staff. Sir Ernest Rutherford occupied the chair, and about 130 other members of the Society were present, while numerous messages of affection and esteem were sent by old students who are carrying on the Cavendish tradition of faithful work and productive insight in many parts of the world. To all of these, 'J. J.' is, what man finally became to Wordsworth, "an object of delight, of pure imagination and of love." He is the uncrowned king of physical science, and it is an honour and an inspiration to have come within his sphere of influence. Something of the spirit of devotion which he creates in all who have been associated with him is expressed in the following address, which was presented to Sir Joseph at the dinner, bearing the signatures of 230 of his disciples :—

"We, the past and present workers in the Cavendish Laboratory, wish to congratulate you on the completion of your seventieth year. We remember with pride your contributions to theoretical and experimental physics, and especially your pioneer work on the structure of the atom The additions you have made to knowledge are conspicuous even in this age of remarkable achievement, and have profoundly influenced the history of science. Succeeding to the Chair of Clerk Maxwell and Lord Rayleigh, you have made the Cavendish Laboratory, during your forty-six years' association with it, an unrivalled centre of intellectual activity. We, who have had the privilege of working with you, cannot adequately measure our debt. We can only express our grateful appreciation of the help, encouragement, and friendship given so freely to all your students, and our hope that you may long live to be an inspiration to the Cavendish Laboratory and the whole world of physical science."

In presenting this address, together with two silver caskets to Sir Joseph and Lady Thomson, Sir Ernest Rutherford related some personal reminiscences of the years—"the happiest in my life"—spent with 'J. J.' in the Cavendish Laboratory, of which he is now the director, and so successfully penetrating into the innermost courts of eternal wisdom. Prof. P. Langevin, representing men of science from other lands, who have worked in the laboratory and been admitted to the freedom of its fellowship, paid a charming tribute of affection to the guest of the evening. Sir Joseph expressed his thanks in an eloquent speech in which, in generous words, he referred to the unselfish support he had received from all members of his staff, and to the ever-expanding field of scientific research which can never be a terminus but is always revealing new avenues to be explored. The toast of "The Old Cavendish Students" was proposed by Dr. A. Wood, who, with Mr. H. Thirkill, organised the dinner; and Sir Arthur Schuster, Sir Richard Threlfall, and Prof. F. Horton, in acknowledging it, bore grateful testimony to the stimulating influence of the laboratory and its directors upon successive generations of students. All who have worked within its walls have acquired a quality of spiritual radioactivity which makes for light and leading wherever they go. But though they take away this emanation with them, there is no weakening of the parent source, which, we are sure, will continue to illuminate the road along which science advances to secure increase of knowledge for the benefit and admiration of posterity.

The Council of the Physical Society, at its meeting on December 10, awarded the fourth Duddell medal for meritorious work on scientific instruments and materials to Mr. F. Twyman. The firm of Adam Hilger, Ltd., of which Mr. Twyman has for many years been both managing and technical director, enjoys a reputation for the production of optical instruments employed in physical research which is not approached by that of any other firm in Great Britain or any other country. The fundamental researches which have led to the formation of the current conceptions of the nature of matter have been carried out to a large extent with the aid of instruments of the necessary high degree of precision constructed in the Hilger workshops. The production of these instruments has frequently involved the solution of problems which have only been met successfully through Mr. Twyman's persistence and resourcefulness.

In addition to the services rendered to the cause of pure science, Mr. Twyman has carried out notable work on a number of technical problems. Two may be specially mentioned. His investigations on the annealing of glass (which incidentally led to Twyman's Law on the influence of temperature upon the mobility of the melt) are of fundamental importance, and his instruments for controlling this operation have been of service to all branches of the glass-making industry. These investigations have been an important factor in securing home supplies of reliable glass-ware for scientific purposes. Moreover, during the War, they led to a notable increase in the output of optical glass, by substituting for the traditional routine a novel scheme of annealing, which, without any deterioration in the quality of the product, enabled the time occupied in this operation to be greatly reduced. As another example of technical work, the extensive series of Hilger interferometers may be mentioned. The Michelson type of interferometer has been modified and adapted to a large number of special uses of interest to the optical industry. By the use of these instruments accurate measurements can now be made of the defects of all manner of optical parts and instruments, whether these defects are due to faulty design, imperfect workmanship, or defective material. It is characteristic of Mr. Twyman that these new instruments were immediately used not merely to measure the defects, but also as a means of removing them.

AT the present time, no problem interests electrical engineers more than the question of the best type of main to use for the underground distribution of electrical energy. In many towns, even the suburban districts are so built over that the use of overhead lines is quite out of the question. As the load increases, the necessity of using very high pressures becomes urgent. It is common knowledge that some of the high-tension mains laid in Great Britain have given a great deal of trouble owing to breakdowns. The paper read to the Institution of Electrical Engineers on December 16 by Colonel E. Mercier on the 60,000-volt underground network operated in Paris by the Union d'Électricité was therefore of great value. The system of distribution most favoured at present is the three-phase system. There are three distributing mains which can either be bound together so as to form a single cable called a three-core cable, or three separate cables can be used. The former solution is that generally adopted in Britain, and the latter is the one adopted in Paris When they are bound together they can be handled more expeditiously, but there are a few drawbacks. The carrying capacity of the cables is limited by their temperature rise. The heat generated in three-core cables has greater difficulty in getting conducted away, and so they carry less current in proportion. The predetermination of their carrying capacities and breaking-down voltages presents much greater difficulty. The rotating electrostatic fields produced in these cables also produce dielectric losses. The great steam-driven station at Gennevilliers in Paris in linked with the station at Vitry and will soon be connected with the hydro-electric station at Eguzon on the River Creuse. The total power of these stations is nearly 500,000 kilowatts. The network connects a ring of distributing stations round the city of Paris. The company's engineers have recently examined the best types of three-core cable and have reported adversely on them for their extensions. They consider that single cables involve a smaller initial outlay, are more trustworthy, and are easier to repair.

THE annual Philosophical Lecture of the British Academy under the Henriette Hertz Trust is always an event of much interest. This year's lecture, which was given in the rooms of the Royal Society on Wednesday, December 15, was no exception, as the lecturer, Prof. T. Percy Nunn, Principal of the London Day Training College, is a man of outstanding ability and experience in the realms of education, mathematics, and philosophy. The subject of the lecture was "Anthropomorphism and Physics." By anthropomorphism Prof. Nunn stated that he means, broadly, the 'projection' of any human character into the non-human world, and in this way it is a trait of primitive mentality which still colours man's dealings with his environment. As Prof. Nunn showed, it has played an important part in the history of science, and even some of the technical vocabulary is an indication of the way in which the human point of view can be projected. Prof. Nunn pointed out that to some, the theory of relativity allows for an anthropocentric view of Nature; whereas the truth about the modern theory of relativity is that it is really one more step further away from the old anthropomorphic ideas, emancipation from which was begun by the work of Copernicus. Prof. Max Planck has said that physical science can only reach unity by eliminating all anthropomorphous elements. The main purpose of the lecture was to inquire how far this elimination can proceed. The first step is to seek a tenable theory of physical objects which presumes the objective existence of secondary qualities; such theories have been formulated by the Realists. The next step is to raise the question of the reality of such objects as electrons which physics offers. The tendency of recent attempts to overcome such difficulties is to show that physics has no need of the hypothetical forms of matter which have been claimed as the reality behind the apparent world.

ANCIENT surveying instruments were described by Sir Henry Lyons in a lecture to the Royal Geographical Society on December 13. In Egypt, records of land measurements are found from very early times, although no map of landed property in ancient Egypt has survived. The marking of province boundaries was also recognised as being of great importance, and operations of levelling reached a satisfactory accuracy, as can be gauged from the rock pavement on which the great pyramid was built. In ancient Egypt the instruments employed in land survey were very simple, and included probably only the measuring cord of 100 cubits, the measuring rod, and the *merkhet* for laying out lines in any desired direction. The *merkhet* consisted of a plumb-line hanging from a holder, which was aligned on any object by looking through a sight vane made of a cleft stick. The levelling instrument was probably a right-angled isosceles triangle of wood with a plummet attached to the apex. In use it was placed on a long wooden straight-edge resting on pickets. Probably not until Greco-Roman times was another instrument, the *groma*, introduced. Egypt may have been its place of origin, but the Romans used it widely. The *groma* consists of two pairs of plumb-lines suspended from the ends of two rods at right angles to one another. Some of these instruments of different designs have been recovered.

ON Tuesday, December 14, a new research laboratory for physical and inorganic chemistry was opened at East London College by Mr. E. de Q. Quincey, the chairman of the College council. This laboratory is the gift of Mr. and Mrs. Henry Cohen, of Beckenham, and is a memorial to their son David, a former student of the College, who died in May 1925. The laboratory is equipped for research work in physical and inorganic chemistry and chemical microscopy, and contains a small library, also the gift of Mr. and Mrs. Cohen. Mr. Quincey, in accepting the gift on behalf of the College council, pointed out that it was a valuable appreciation of the necessity of assisting advanced work at the College, and expressed the hope that other old students would follow this excellent example. The

Principal of the College and Prof. J. R. Partington, in whose department the new laboratory is situated, both emphasised the importance of a period of study after graduation to students entering industry or the teaching profession.

In the House of Commons on December 15 Mr. W. Baker asked the President of the Board of Education whether his attention had been directed to the planetarium invented by the firm of Zeiss and erected by the Düsseldorf Corporation. The firm declines to supply these structures to any one proposing to make a profit, and having regard to educational possibilities and the poverty of educational authorities, Mr. Baker asked whether the Board would consider the purchase for educational purposes of at least one planetarium. The Duchess of Atholl, Parliamentary Secretary to the Board of Education, who replied, stated that the Board of Education has no power under the Education Act, 1921, to make a purchase of this kind. Two years ago a planetarium was installed at Munich, and a description of the apparatus appeared in Nature of December 27, 1924, p. 937. According to a letter from Dr. J. Jackson in the *Times* of December 20, the success of this instrument led Messrs. Zeiss to build a larger and improved planetarium for Jena, while similar instruments have been made, or are on order, for Barmen, Berlin, Dresden, Düsseldorf, Hamburg, Hanover, Leipzig, Mannheim, Nürnberg, Stuttgart, and Copenhagen.

At the ordinary scientific meeting of the Chemical Society held on December 16 the president, Prof. H. Brereton Baker, announced that the Council had unanimously resolved to award the Longstaff medal for 1927 to Prof. Robert Robinson of the University of Manchester for his distinguished researches in organic chemistry. It was also announced that, in accordance with the terms of the trust-deed establishing the Edward Frank Harrison Memorial Prize, the selection committee, consisting of the presidents of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry, and the Pharmaceutical Society, had met to consider applications for the Harrison Memorial Prize. This prize, it will be recalled, is awarded to the chemist of either sex, being a natural-born British subject and not more than thirty years of age, who in the opinion of the selection committee has, during the past five years, conducted the most meritorious and promising original investigations in chemistry and published the results of those investigations in a scientific periodical or periodicals. The selection committee has unanimously resolved that the prize for 1926, of the value of 150*l*., should be awarded to Dr. Charles Robert Harington of University College, London. Dr. Harington has within the last five years synthesised the active principle of the thyroid gland (thyroxine); he has determined its constitution and worked out a practical process by which it may be produced on a large scale. This artificial product has been found to have the same physiological efficacy as the active principle in the natural extract. The presentation of the Longstaff medal and of the Harrison Memorial Prize will take place at the annual general meeting of the Chemical Society on March 24, 1927.

The Kamerlingh Onnes Memorial Lecture of the Chemical Society will be delivered by Prof. Ernst Cohen of Utrecht, at the Institution of Mechanical Engineers, Storey's Gate, S.W.1, on Thursday, February 10, 1927, at 8 P.M.

Dr. A. B. Walkom, secretary of the Linnean Society of New South Wales, has been granted twelve months' leave by the council of the Society to enable him to study palæobotany under Prof. A. C. Seward at Cambridge.

Mr. Heron-Allen has presented the Heron-Allen and Earland collection of Foraminifera to the British Museum (Natural History) under conditions which will enable him and his collaborator to keep it up-to-date, with additions and rearrangement. The collection, which numbers between seventeen and eighteen thousand slides, includes the Millett, Siddall, Sidebottom, and other notable collections, and is undoubtedly the largest and most complete in the world.

The annual meeting of the Science Masters' Association will be held at Oxford on January 4-7, under the presidency of Brigadier-General H. Hartley. The meeting includes lectures by distinguished scientific workers at Oxford, and an exhibition of apparatus and books at the Electrical Laboratory, Parks Road. The organising secretary for the meeting is Mr. W. J. Gale, 50 Stanton Road, Wimbledon, London, S.W.20.

The Eastern Siberian section of the Russian Geographical Society announces the celebration of its seventy-fifth anniversary at the end of this month. The occasion is to be marked by various social functions and an exhibition illustrating the results of the Society's work in Siberia. Various publications are also announced, including the fifteenth volume of the *Isvestia*, with a series of historical articles and a volume of general geographical and statistical articles on Eastern Siberia. These publications are apparently to be in Russian.

The Buchan Prize of the Royal Meteorological Society for 1927 has been awarded to Mr. C. K. M. Douglas for the following papers contributed to the *Quarterly Journal* of the Society during the years 1922–25: "Observations of upper cloud drift as an aid to research and to weather forecasting"; "Further researches into the European upper air data, with special reference to the life history of cyclones"; "On the relation between the source of the air and the upper air temperature up to the base of the atmosphere"

An interesting exhibition of some of the results of research recently carried out in adhesives (glues and sticking substances) and their application has been arranged at the Science Museum, South Kensington, by the Adhesives Research Committee of the Department of Scientific and Industrial Research.

This Committee was established by the Department in 1919 to continue the work of the Adhesives Research Committee of the Conjoint Board of Scientific Societies which was set up towards the end of the War to conduct research on adhesives with the aid of a grant from the Ministry of Munitions. The exhibition was opened to the public on Saturday, December 18, and will remain open for some months.

A BROCHURE on electro-medical apparatus by Messrs. Newton and Wright, Ltd., 72 Wigmore Street, London, W.1, gives a fairly complete list of appliances in current use with illustrations and prices. These appliances include portable sets required for administering faradic or galvanic currents. An electro-medical table shown has all the requisite gear for giving both varieties of current from any D.C. supply between 50 and 250 volts. There is also illustrated an "Omnistat" machine in which the motor is an integral part of the apparatus, which is made in two models; the "Standard," providing galvanic and sinusoidal currents; and the "Therapeutic," in which the faradic is substituted for the sinusoidal. Both types are adapted for the inclusion of vibro-massage apparatus.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant master at the Dewsbury Municipal Technical College, with qualifications in physics and electrical engineering—The Secretary for Education, Education Offices, Town Hall, Dewsbury (January 3). An assistant lecturer in physics at the Bradford Technical College—The Principal (January 11). A director of tubercular research in the University of Melbourne—The Agent-General for Victoria, Victoria House, Melbourne Place, Strand, W.C.2 (February 1). Assistantships in the departments of zoology, botany, entomology, and mineralogy of the British Museum (Natural History)—The Director, British Museum (Natural History), South Kensington, S.W.7. A teacher of engineering subjects and metalwork at the Doncaster Technical College—The Principal, Technical College, St. George Gate, Doncaster.

Our Astronomical Column.

RECENT SUNSPOTS.—The stream of spots seen near the sun's central meridian on Dec. 15 and 16 is the most important group observed for the last two months. Except for occasional short intervals, there has been no dearth, however, of smaller spots, whilst faculæ have been abundant (see also NATURE, Oct. 23, p. 603). The spots recently under observation appear to have originated about Nov. 21, but cloudy weather prevented their development being followed at that time, and later when the group was due to return at the east limb on Dec. 9. When first seen on Dec. 15, the arrangement of the spots was that usually associated with a bipolar group or stream of normal type. With the exception of the leader, the component spots were much broken up. The length of the stream, which was parallel to the sun's equator, was about 12° of solar longitude. Although the aggregate area of the spots was fully 1000 millionths of the sun's hemisphere, the group could be seen on Dec. 15 and 16 only when the disc was very carefully screened. Particulars of position, etc., are given below. It may be noted that no group so large as this has hitherto appeared during the present cycle so close to the sun's equator.

No.	Date on Disc.	Central Meridian Passage.	Latitude	Area.
11	(Dec. 9–22)	Dec. 15·9	7° N.	1/1000 of sun's hemisphere

THE DOMINION ASTROPHYSICAL OBSERVATORY, VICTORIA, B.C.—Vol. 3, Nos. 9, 10, 11, 12 of the publications of this observatory, deal with the orbits of nine spectroscopic binaries and the radial velocities of 48 stars. 12 Lacertæ is interesting from the rapid change in the amplitude of the radial motion, accompanied, according to Guthnick, by a similar change in the range of variability of light. As in many other cases, the *H* and *K* lines of calcium are stationary, and nearly accord with the solar component of radial motion. The 48 stars were found to include 9 binaries.

Boss 1275 was found to be a binary by Adams at Mt. Wilson in 1916, but the period previously adopted, 27·43 days, is shown to be wrong. The true value is 2·15165 days.

H. D. 191201 is a very massive binary, the minimum values for the components being 13·8 and 12·9 times the sun. The type is B0, and the estimated distance 5000 light years.

U.S. NAVAL OBSERVATORY, WASHINGTON.—Vol. 10 of the publications of this observatory deals, in the first place, with observations made with the Prime Vertical Instrument during the period 1893–1912. Vega was the star most regularly observed, since it is readily visible by day. It was found, however, that the daylight observations differ systematically from the night ones; the difference is ascribed to lateral refraction produced by unequal heating of the layers of air near the instrument.

The parallax of Vega was deduced to be 0·123″, the aberration constant 20·542″, the nutation constant 9·250″, the mass of the moon 1/80·54. The last was deduced from the nutation constant, assuming the luni-solar precession for 1850 to be 50·373″. The variation of latitude was not deduced from the observations but was taken from the values published by the International Geodetic Association.

The volume also gives in detail the results obtained during the total solar eclipses of 1905, 1918, 1923. Two expeditions were sent to Spain and one to Algeria in 1905. Numerous plates contain reproductions of the coronal photographs and also of drawings, both those made direct from the corona and those from combinations of photographs. There are some excellent reproductions of the chromospheric spectrum; in one plate this is placed in juxtaposition with the corresponding region in Rowland's Atlas.

Some striking drawings in colour of the landscape (showing approach of moon's shadow) and of the corona and prominences were obtained in 1918 by Mr. Howard Russell Butler, and are reproduced in colour in the volume. He gives the corona a distinct blue tint, agreeing with several observers, though others describe it as white. The distant hills in the shadow are drawn as purplish violet; the sky just above them in orange, changing to bluish purple higher up. The orange band was also seen in Norway in 1896, when Mr. N. E. Green made a colour drawing of the landscape during totality. The eclipse of 1923 was observed from aeroplanes; interesting descriptions are given, but they are of little scientific value.

Research Items.

HYDROIDS OF THE *VALDIVIA* EXPEDITION.—The account of the hydroids of the German Deep Sea Expedition (*Valdivia*) ("Hydroiden der Tiefsee-Expedition," bearbeitet von Prof. Dr. Eberhard Stechow. Wissenschaftliche Ergebnisse der Deutschen Tiefsee-Expedition auf dem Dampfer *Valdivia*, 1898–1899, Bd 17, Hft. 3. Jena, 1925) is a valuable contribution to coelenterate literature For some years Prof Stechow has published papers in various journals showing that these hydroids are of a peculiarly interesting nature, and now we have a comprehensive survey of them all. In this material twenty-five per cent. of the species are new and there are two new genera. The author is of the opinion that whilst there are many bipolar genera, the species from the Arctic and Antarctic are themselves distinct, and many examples of confusion of species are here cleared up and thoroughly investigated. Only fourteen out of one hundred and twenty-four species described are medusa-bearing forms. The reason for this is attributed to the presence of ice, which is inimicable to medusæ. The same is found to be the case in Arctic seas. In the coldest regions the medusa-bearing hydroids are almost completely absent This subject has already been discussed by the author in 1924 ("Über den Einfluss der Temperatur auf die Erzeugung von freien Medusen, etc," *Verh d. Deutsch Zool. Gesellsch*), and the facts are plainly shown in the present records There are some extremely interesting hydroids amongst this *Valdivia* material. To mention only a few of the most striking, we have the soft parts of *Hydrocorella africana* described, of the family Bougainvilliidæ, having a skeleton of almost pure lime composed of small spines and large horns and bearing sporosacs. This is perhaps the most interesting of the athecate forms. Most of the remaining species belong to the Thecata. Here amongst the Plumulariidæ is the aberrant and very extraordinary *Dinotheca Dofleini*, already briefly described by Prof. Stechow in *Zoologischer Anzeiger*, vol 37, in which there are probable affinities with the Graptolites (Rastrites) Altogether an enormous amount that is new is to be found in this most excellent monograph, and the beautiful series of figures in simple outline adds much to its value

THE STATOCYSTS OF CEPHALOPODS —M. Ishikawa (*Jour Coll. Agr.*, Imp Univ., Tokyo, 7, No 3, 1924, recently received) has studied the statocysts of 59 species of Cephalopoda principally from Japanese localities. The statocyst was removed and cut transversely into two halves; the internal structure and the processes developed on its wall and projecting into the lumen were then examined. In the Octopoda only one process (labelled *c*) is present, and a corresponding one is found in all cephalopods. In Argonauta and Tremoctopus this process is unbranched, while in Ocythoe and Polypus it is provided with two small knobs, and the author suggests that the two former genera are more primitive than the two latter. In the Decapoda the genera can be divided into two series according as a process *b* is present (in four genera) or absent (in nine genera) In the latter group the processes are two only in the genus Pyrgopsis, nine in Cranchia, ten in Watasenia (and four other genera), eleven in Ommastrephes (and five other genera), and twelve in Loligo and Sepioteuthis Of those in which the *b* process is present Idiosepius exhibits five processes, Sepia eleven, Sepiella twelve, and Thysanoteuthis thirteen A phylogenetic tree is shown based on these details, and the author points out that the arrangement is in accordance with other characters, *e g* the fins, the shell, and siphonal joint apparatus. Young specimens of a Sepioteuthis were pricked with a needle so as to injure the statocyst of one or of both sides. When the left statocyst was injured the animal moved in a clockwise direction; when the right one was pricked movement was in the reverse direction, and when both statocysts were destroyed the swimming became quite irregular

NUCLEAR DIVISION IN *Entamœba histolytica* —Two accounts of nuclear division in *Entamœba histolytica* (*dysenteriæ*) have appeared recently One of these, by Prof C. A Kofoid and Dr. O Swezy (*Univ. Cal. Publ Zool*, vol 26, No. 19, 1925), is based chiefly on a study of cysts found in freshly examined human fæces. The karyosome migrates from its previously more or less central position towards the nuclear membrane and divides into two parts which draw out the intradesmose between them as they pass to the poles of the spindle, where they constitute the polar caps. These caps are thus in the position of the centrosomes, but a centriole was seen at the ends of the intradesmose only in two examples, both from the cat. The source or sources of the six chromosomes were not fully traced. By this time the nucleus is spindle-shaped, and the chromosomes divide in a seemingly transverse plane but in reality in the end-phases of a longitudinal separation The two groups of chromosomes migrate towards the poles and the nucleus constricts into two. The second paper, by C Uribe (*Proc. Nat Acad. Sci.*, 12, 1926, pp 305-311), is based on observations of numerous trophozoites in a cat which had been experimentally infected. Division stages were observed both in amœbæ which had invaded the intestinal wall, and in others on the surface of the epithelium The poles of the dividing nucleus are pointed, and each terminates in a clear cone at the apex of which is a small centriole The number of chromosomes is six; after their division the resultant daughter chromosomes move towards the poles. The two daughter nuclei are about this time connected only by an elongate thread which later snaps and then the chromatin becomes distributed on the nuclear membrane The clear cone and the centriole persist in the daughter nuclei after their separation but disappear with the formation of the karyosome Apparently only a part of the 'peripheral chromatin' is incorporated in the chromosomes of the dividing nucleus.

THE PROTOZOA OF THE PITCHER PLANT.—"Primitive conditions of digestion might be expected in insectivorous plants, and this idea is responsible for the investigation"—by Prof. R. W. Hegner (*Biol. Bull*, 50, 1926) of the protozoa of the pitcher plant—in connexion with the general problem of the relationship between intestinal protozoa and their environment. Ten pitchers (*Sarracenia purpurea*) from different localities in Maine were carefully examined, and in all of them protozoa were present—all three classes being represented by several species. The liquid from many other pitchers was examined and similar protozoa found in most of them. The most common organisms in the pitchers were insect larvæ, mites and rotifers; nematodes and Entomostraca were found in a few, and Tardigrada in one pitcher. The protozoa in the pitchers are probably free-living species carried in by flies, though some of them may be restricted to this environment Paramœcia from a culture were placed in the fluid in or obtained from the pitchers, and were found to be able to live therein for an indefinite period, and in some cases to multiply. Colpoda and Chilomonas could also live in the fluid and multiply.

ARACHNIDISM —In two papers recently published (*Jour Amer. Med Assoc.*, 86, 1926, 1894; *Arch. Int. Med*, 38, 1926, 623), Dr. E. Bogen, of Los Angeles, brings forward evidence that poisoning by spider bites, on the reality of which a good deal of doubt has been thrown, is quite a material thing. The effective spider in California is *Latrodectus mactans*, which lives in outhouses and similar places and has an unfortunate liking for closet seats. Symptoms come on at once or within a few hours, and consist mostly of agonising general pains which need large doses of opiates to control them. The patients recover in a few days without any after-effects. Poisoning by allied and other spiders is well-established in southern Europe, Madagascar, Australia, and South America, and though the tale of the tarantula is of course a myth, arachnologists seem to have gone too far in doubting the possibility of human poisoning altogether.

A NOVEL GEAR —In many classes of machinery it is required to vary at will the relative speed of one shaft driven by another. This has usually been done by means of gear-wheels, chains, or belts. With toothed wheels, however, the number of changes are few, while with belts slipping occurs. To increase the number of changes and at the same time to prevent slipping, a novel type of drive has been invented which, in the main, resembles the belt drive between opposed conical discs so commonly used on lathes. In this invention the faces of all the cones have alternate ribs and grooves radiating from the apex, while in each link of the chain are fitted a number of thin steel slats which, while they project sufficiently to engage with the ribs or the cones, have a certain amount of freedom endwise. There cannot thus be any slip, while by closing one pair of cones and opening the other the relative speeds can be altered. The gear is called the " Positive Infinitely Variable " or " P.I.V. Gear," and has been placed upon the market by a syndicate bearing the same name Trials of the gear have been carried out at the National Physical Laboratory, and these show that under favourable conditions an efficiency of 95 per cent can be obtained. One example of the gear was shown at the Textile Exhibition at Leicester in October, where an A.C motor running at 1000 R.P.M. drove another shaft at speeds varying from 250 to 500 R.P.M. The invention is an ingenious one, and provided that the chain does not show abnormal wear with prolonged use, it should have many applications.

LOADING SUBMARINE CABLES.—The competition that has arisen between high frequency radio and submarine telegraphy has accelerated the development of the latter method of communication The greatest recent improvement is the use of cables the cores of which are surrounded by what is practically a cylinder of metal (permalloy) tape which has a very high permeability for very minute magnetising forces The theory of the transmission of signals in this kind of cable was first clearly explained by Oliver Heaviside. His predictions as to the great speeding up that could be effected by a ' uniformly loaded ' cable have been verified in practice. The New York-Azores permalloy loaded cable is perhaps the best-known cable of this type and it works at a very high speed A factor, however, limiting the speed of cables of this type is the mutilation of the received signals by electrical disturbances picked up along the cable and transmitted with the incoming signal to the receiving instrument. In a paper published in the *Bell System Technical Journal* for July 1926, J. J. Gilbert explains how this difficulty has been overcome in the New York-Azores cable At the New York terminal the ocean is comparatively shallow for a distance of about 100 miles. This part of the cable is therefore exposed to atmospheric disturbances and to strong stray fields from the numerous electric railway systems near New York. The Azores end of the cable reaches very deep water after a few miles and is therefore almost completely protected from atmospheric and other disturbances. To prevent the disturbances that experiment showed would otherwise be introduced into the cable at New York, a simple and effective remedy was devised. The earth terminal of the receiving apparatus was connected to the armouring of the cable by means of an insulated cable taken one hundred miles out to sea. This method is entirely successful and the highest speeds can be maintained Mr Gilbert's theory of this new type of sea earthing device is clear and convincing.

WROUGHT MAGNESIUM AND MAGNESIUM ALLOYS. —Report No 1037 of the Engineering Research Board of the Department of Scientific and Industrial Research, by S. L Archbutt and J. W. Jenkin, deals with magnesium and magnesium alloys The use of this metal and its alloys is of considerable importance where the saving of weight is a first consideration, as this metal is much lighter than aluminium. Cast magnesium alloys have already been used in aeroplane engines, and the present work commences a research to fill the gap in the knowledge of the wrought alloys. The materials chosen are the metal itself, its alloys with 3 and 13 per cent of copper, with 6 per cent. of aluminium and the proprietary alloy ' electron,' the composition of which is given as . zinc 4·38 per cent, silicon and aluminium 0·15 per cent each, and copper 0·22 per cent, the remainder being magnesium. The melting and rolling of the alloys are described in detail. Typical values of the mechanical properties of 1 in hot-rolled rod at atmospheric temperatures are :

	Magnesium	6 per cent. Aluminium Alloy.	Electron
Limit of proportionality, tons/sq in . . .	1·60	2·40	4·9
Maximum stress, tons/sq in .	15·7	18·2	17·8
Elongation per cent on 2 in	12·5	20·0	11·6
Reduction of area, per cent	19·0	22·0	18·7
Wohler endurance limit, tons/sq in. .	4·5	6·5	.
Impact, ft lb . .	4·0	4·8	
Brinell hardness (500 kgm load)	39	50	58

The effect of prolonged heating to 350° C. has been determined for the first two of these materials. There is a decrease in both the maximum stress and the elongation. The impact test, however, shows that no embrittling accompanies this loss of elongation, the energy absorbed actually increasing very markedly in the case of the alloy. The Brinell hardness of all the materials has been determined at temperatures up to 350° C. and complicated changes are observed.

HYDRION CONCENTRATION AND PHOTOGRAPHIC EMULSIONS —Under this heading reference was made in NATURE of December 18, p. 893, to a paper by Rawling and Glassett (*Journal of the Royal Photographic Society*, November). It was stated that " the photographic sensitiveness obtained after digestion is greater as the hydrion concentration is increased." This is incorrect; sensitivity increases as the hydrion concentration decreases.

Stress and Rhythm in Speech.

NOTWITHSTANDING the steady advance of knowledge concerning the physics of speech, with regard to certain of the most fundamental speech-phenomena a lush upgrowth of theory has yielded a very small crop of ascertained facts. Especially is this true concerning speech-rhythm. The reasons are several. Too frequently investigators have failed to formulate their problem with precision and have obscured it with terms of undetermined connotation, such as 'stress,' 'accent,' 'quantity,' even the word 'measurement' being very loosely used; most serious, however, has been their failure to appreciate or apply the methods evolved by other sciences for solving kindred problems.

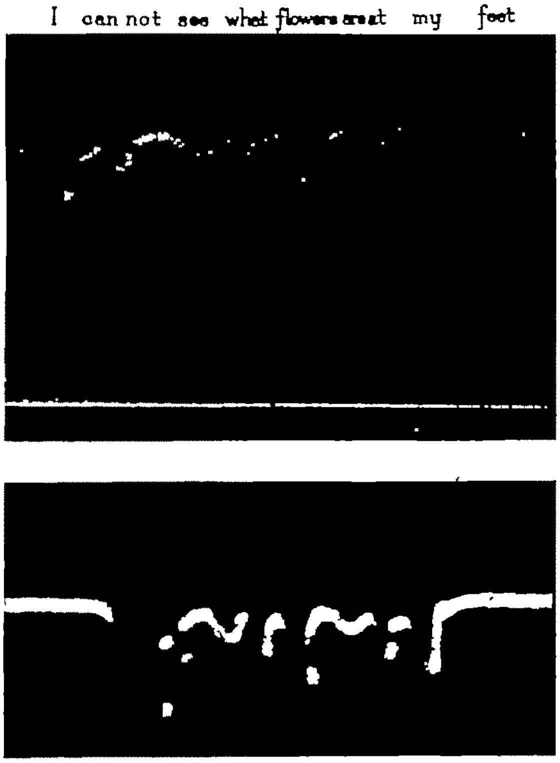

FIG. 1.—Direct photographs of jaw-movement. The lower curve was recorded some months after the upper, but by the same speaker. All the characteristics of the first curve are reproduced in the second, but the latter is more compressed laterally owing to slower movement of film.

Physiological research during the past half-century has shed complete light upon certain rhythms and, in so doing, elaborated characteristic and efficacious methods. A typical case is that of the heart-beat, which presented itself primarily as an *audible* rhythm, but could be subjected to accurate mensuration only when compelled to leave a *graphical* record upon a surface moving with known speed, *i.e.* when time had thus been replaced by its spatial presentment, alone susceptible of measurement. Let the metrician consider the principle involved. Behind the acoustic record of rhythmical sound, the true amplitudes of which were difficult of discovery, the physiologist was interested in the muscular actions, themselves presumably rhythmical, by which it was generated, and he addressed himself to the direct recording and measurement of these, incidentally presenting the metrician with an instructive but neglected example.

Experiments which I have been enabled to carry out during the past few years in the Physiological and Phonetics Laboratories at University College, London, indicate that even a crude adaptation of the physiologist's method yields valuable data as to the nature of 'stress,' and the distribution along the time-line of speech of its moments of maximum incidence. Fig. 1. exhibits the track marked on a photographic film, moving with uniform velocity, by an electric spot-light fixed rigidly between the lower incisor teeth of a speaker who, in profile to the camera and in darkness, recited the line "I cannot see what flowers are at my feet." It represents, therefore, the rise and fall of the jaw during utterance. I can discuss here only one or two of the problems and conclusions suggested by this and very numerous similar experiments. It seems surprising that previous investigators should have neglected to examine this most evident factor in normal speech—the opening and closing of the mouth. The movements involved can scarcely be adjudged *a priori* superfluous and insignificant, since every depression of the jaw, effected by the combined work of numerous muscles and more particularly of those attached to the hyoid, provokes, as anatomists are fully aware, very special pivotings and displacements of the thyroid cartilages supporting the glottis, and consequently special tensions and special modifications of the resonant cavities of mouth and pharynx. These modifications are strictly conditioned by the number of muscles brought into play and the speed and vigour with which they are contracted. Hence the tracing executed by the moving jaw is a valuable index of the whole process of phonation, and this tracing reacts characteristically to every variation of stress, pitch, and vowel quality (timbre). The stressing (emphasising) of any particular vowel involves increased vigour of jaw-movement, and for each timbre characteristic degrees of descent of the jaw and characteristic expenditure of time.

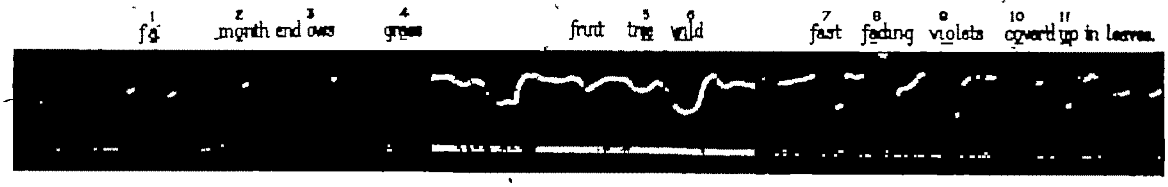

FIG. 2.—Excerpts from a continuous film of jaw-movement: "Wherewith the favourable (*sic*) month endows The grass, the thicket, and the fruit-tree wild," "Fast fading violets covered up in leaves." 1 and 8: characteristic semi-circular trough for a in fading and favourable. 2, 10, and 11: peaked trough for vowel Λ in mouth, covered, up. 4 and 7. characteristic right-hand ascent of trough representing a in grass and fast. 3, 6, and 9 large diphthong troughs in endows, wild, violets. 5: compare trough of i in fruit-tree with that of i in see (Fig. 1).

In Fig. 1 the vowels occupy the wave-troughs, and it will be realised that the lowest point of each trough, *i.e.* the point of maximum stress, corresponds to a unique position of the vocal apparatus, achieved by increasing muscular contractions on the descent and unmade by reversal of these contractions on the ascent. A 'pure' vowel apparently consists of symmetrical phases of approach and recession about

e char-
s of different

d of tracing. Instead

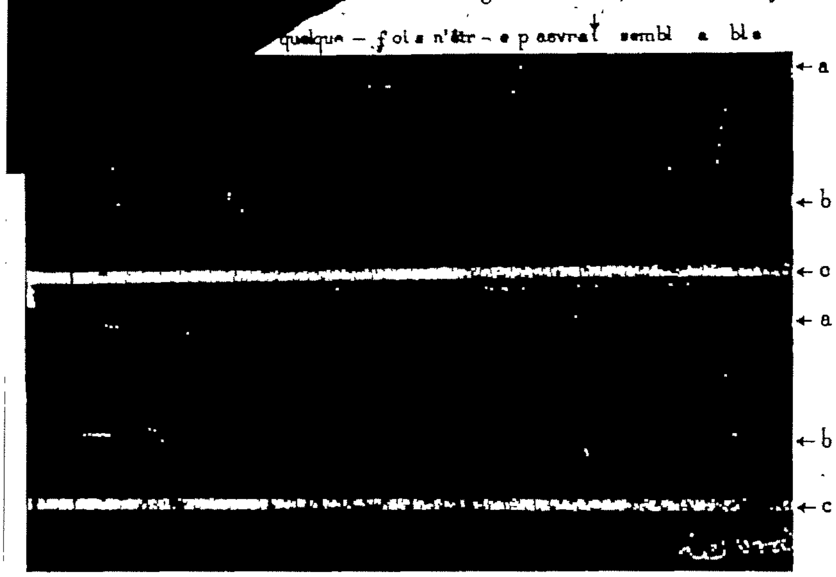

FIG. 3.—Two recitations of "Le vrai peut quelquefois n'être pas vraisemblable" (a) Jaw-movement; (b) sound record; (c) time record (tuning fork, 100 vibrations per sec.).

of the direct photograph of jaw-movement we have here (*a*) an inscription made by the lever of a Marey-tambour fitted with an extremely elastic soft rubber diaphragm and hermetically connected with a bulb carried on a plate under the speaker's chin in such a manner as to eliminate the influence of all head-movements other than those of the jaw, the latter being recorded in terms of air-pressure. The figure contains the inscription of two recitations of the French Alexandrine, "Le vrai peut quelquefois n'être pas vraisemblable." The total time taken by each recitation is 2¼ seconds between the lowest point of the first vowel trough lE and the lowest point of the last, vraisemblAble. It will be observed that the same intricate curve is reproduced with scrupulous fidelity, and, as this reproduction postulates the identical performance of many highly complex and varied acts by a synergy of numerous muscles, it is difficult to believe that this fine accuracy subserves no practical purpose. It is interesting to observe the different depth and shape of trough corresponding to the vowel *ai* (e) in vr*ai* and in vr*ai*semblable, that is, in circumstances of strong and weak stress respectively. The inscription of jaw-movement is accompanied by simultaneous records (*b*) of sound vibrations, registered by the usual phonetic tambour, and (*c*) of the vibrations of a tuning-fork (100 per. sec.). Clearly by synchronising these three tracings we can determine to what phase of jaw-movement each sound corresponds and the time relations between the points of maximum stress. Most of the records thus synchronised have been registered on surfaces moving at a rate of about 10 in. per sec. and permit of accurate time measurements to within a 200th of a second.

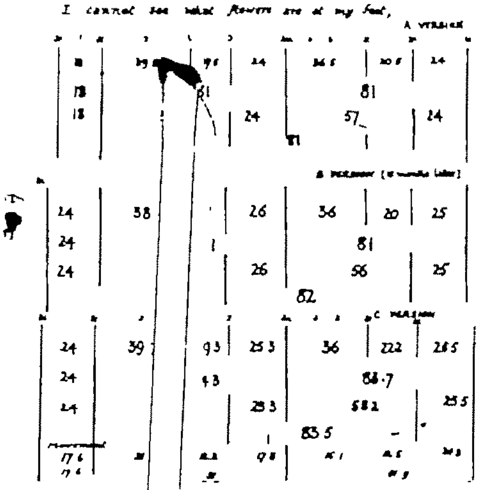
Detailed study of these curves soon reveals a host of unsuspected phonetic data of which the mere summarisation would require more space than is here available. The consonants, according to their nature, can occur only at very definite places on the curve;

and controls and degree and quality of contact. In fine, the observer is able to watch in operation those very factors that have proved so profoundly influential in the historical evolution of speech-sounds.

The utility of the curves for the mensuration of poetical rhythm, a subject of greater interest to the general reader, can be more succinctly exemplified. We give below two sets of figures typical of those obtained from the mensuration of many experimental tracings of the kind described. To guard so far as possible against chance numerical coincidences, each experiment has been performed in duplicate or triplicate, *i.e.* the speaker has repeated his lines two or three times. In more than one case, after the corrections necessitated by the slight variations in speed of the best-regulated kymograph had been made, the recitation-curves, complex though they were, were found to be absolutely superposable; in others they had been systematically and proportionately varied and reflected slight alterations in the speaker's *tempo*.

In the following tables each vertical line must be supposed drawn through the lowest point of the trough of the vowel of which the symbol figures at the top of that line; the numbers give the time, in 100ths of a sec., taken by the voice in passing from lowest point to lowest point.

I. Three recitations of the line, "I cannot see what flowers are at my feet."



I cannot see what flowers are at my feet,

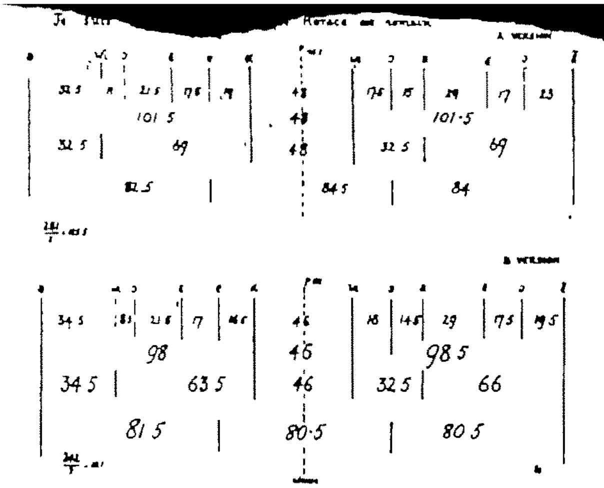
It is scarcely
site to insist upon the constant
evidence of ord
ess displayed by these figures.
Excluding the i
interval, the time falls into two
equal groups—e
beyond the metrician's dream—
delimited by tw
ominent stress-maxima; each of
these groups is a
symmetrically subdivisible. The
very weak stres
as may be judged from Fig. 1)
show no measur
maxima.



Here in each recitation the addition of intervals results in a central symmetry of identical design the [illegible] second Div[illegible] chronising this po[illegible] to coincide with the [illegible] same holds true for B v[illegible] say, the '-cæsura,' though n[illegible] situated exactly midway betwe[illegible] stress-maxima. This twin experim[illegible] interesting as revealing (*a*) a stress-[illegible] French verse, (*b*) the manner in which a rec[illegible] ducing his total time expenditure by 9 in 251 h[illegible] of a second, yet accurately apportions the red[illegible] as to maintain the same organic rhythmical structure.

In this preliminary account of a few among a very large number of experiments, I have been compelled to choose only short examples, and to give of these a very summary interpretation. I may, perhaps, add that more extended records, notably those embracing a complete stanza, yield time-forms of beautifully elaborate and accurate symmetrical structure.

J. W. JEAFFRESON.

Dutch Pendulum Observations in the Atlantic and the Pacific.

By Dr. J. J A. MULLER.

THE voyage of Dr. Vening Meinesz announced in NATURE of June 5, 1926, has almost been completed. The latest information by letter was from Honolulu; a cablegram reported the arrival at Amboina on November 25.

H.M. Submarine *K XIII.* left Helder on May 27 on a calm, sunshiny day, but the weather soon changed and after leaving the channel it was impossible to make any observations above the slope to the deep sea. A few days before sailing the ship had taken in much cargo, especially liquid fuel, and the trim was not known, which made it inadvisable to submerge for the first time in a very rough sea. The first observation was made June 2, and nearly every day after this date while at sea the pendulum apparatus was used in the submerged ship, on several days more than one and sometimes so many as four observations were made As on his former voyages, Dr Vening Meinesz also measured the intensity of gravity in every harbour where the submarine called.

The new apparatus has fully answered to expectations; the pitching of the ship causes no troublesome disturbance, and sliding of the pendulums need not be feared. This apparatus can be used in circumstances in which that used during the former voyage would have failed. A rolling of 3°·5 to both sides was no hindrance to the making of observations. This was a great advantage, as in the Atlantic, at a depth of 20 and more metres, the rolling sometimes reached as much as this The strong swell in the Atlantic and the Pacific destroyed the hope that it might be possible to make observations at the surface of the sea

Unfortunately for the deep sea soundings, the senders of the underwater clock signals were placed too high in the shipboard, in the wave zone. The echo was not a definite sound, and consequently the echo method could not be used for soundings at the surface of the sea; in the submerged vessel the place of the senders caused no trouble. The sonic depth-finder, which had been received only a few days before departure from Helder, has been of no use. Before San Francisco was reached, again and again Commander van der Kun and Dr. Vening Meinesz when trying to detect what was wrong, thought at first it was due to the relay; at length it appeared to be a defect in the construction, which only the maker in London can put right. It is a disappointment that owing to these two circumstances the voyage will contribute in only a limited manner to our knowledge of the depth of the sea on the track. For the determination of the interval of time between the production of the sound and the perception of the echo, a stop-watch of the Royal Navy was used indicating a hundredth part of a second.

The time signals used were at first those of Bordeaux, which were audible so far as Mona Passage, and afterwards those of Annapolis, which could be perceived for some days after leaving San Francisco. The use of the signals of Balboa and San Diego could be dropped, and the Naval Observatory at Washington was informed that these stations need not be controlled. In the whole Pacific the time signals of Lembang, given by the powerful radio station of Malabar (Java) can be used; these were clearly audible in Curaçao. The Nardin chronometers were the same as were used on the voyage in 1925; the regularity of the run of both was marvellous. For the comparison of the chronometers with the rhythmic time signals, Dr. Vening Meinesz intercalates the interrupter of the mean time chronometer in the telephone circuit and observes the appearance and the disappearance of the time signals; in this way the personal equation is almost entirely eliminated.

After taking an observation, the film was as a rule immediately developed; often it was directly measured and the preliminary result computed. Only when the temperature was too high was the developing put off until the next harbour was reached. Dr. Vening Meinesz estimates that the difference between the preliminary results will not exceed 0·005 cm./sec.[2], the isostatic reduction, however, will produce much greater differences. In this connexion it will be wise not to arrive at far-reaching conclusions immediately with regard to the prevailing theories of the constitution of the earth's crust, but to wait until the final computations are to hand.

The number of observations on sea at the different passages so far as Manila is as follows ·

Helder—Horta . .	May 27-June 6 :	4,
Horta—Las Palma .	June 9-June 14 :	5,
Las Palmas—Curaçao .	June 21-July 8 ·	17,
Curaçao—Coco Solo .	July 20-July 24 :	4,
Balboa—Mazatlan . .	July 30-Aug. 10 .	12,
Mazatlan—San Francisco	Aug. 17-Aug. 24 .	8,
San Francisco—Honolulu	Sept 7-Sept. 20 :	15,
Honolulu—Guam . .	Oct. 2-Oct 21 :	20,
Guam—Manila . .	Oct. 28-Nov. 8 :	12.

The total number is 97; up to November 8 the number of observations made at sea and in the harbours is 106 altogether.

With the reservation just made, I give the following particulars about the anomalies shown by the preliminary results. The anomalies refer to the Helmert formula of 1901 and are expressed in cm./sec.² or dynes.

The first observation gave a normal gravity :

June 2, 44° 12' N, 15° 33' W., sea-depth 3000 metres, anomaly +0·004.

The three following gave an excess :

June 3, 43° 13' N, 18° 46' W, sea-depth 4350 metres, anomaly +0·055

" 4, 41 33 21 57 " 4000 " " +0·042

" 5, 39 48 24 57 " 3550 " " +0·062

The last was above the mid-Atlantic ridge.

At Horta the anomaly was +0·126.

Eastward from the ridge the anomaly diminished to 0·016; near the north coast of Teneriffe the coast effect was shown by an anomaly of −0·008.

At Las Palmas the anomaly was +0·210. According to a communication from Dr Bowie, it is reduced to +0·089 by applying the isostatic correction.

After leaving Las Palmas the first three observations gave the following anomalies :

June 22, 27° 12' N., 17° 51' W., sea-depth 3610 metres, anomaly +0·040

" 23, 26 33 21 39 " 4630 " " +0·029

" 24, 25 43 25 19 " 4820 (?) " " +0·030

On July 25, the sea being very smooth, an observation was made at the surface, but at intervals a heavy swell occasioned excessive amplitudes of the pendulums and no result could be obtained. The attempt has not been repeated.

On the following days the anomaly amounted to from +0·015 to +0·029 as the sea-depth diminished from 6400 to 3940 metres. The next observation was made on the ridge.

June 30, 23° 21' N., 47° 2' W, sea-depth 3460 metres, anomaly +0·046.

On July 1, sea-depth 4520-5820 metres, the anomaly was +0·030

In the Atlantic between 32° and 54° W. the depth of the sea often showed great changes; the interval between the sound and the echo varied in the moving vessel in a few minutes by several seconds and then again returned to its former value The sea bed seems to be extremely rugged there. The sea-depths also showed great differences from those given on the "Cartes bathymétriques des Océans" of the Prince of Monaco.

Farther west the gravity was normal :

July 2, 22° 45' N., 54° 35' W., sea-depth 5760 metres, anomaly +0·002

" 3, 22 17 58 27 " 5640 " " +0·002.

Getting nearer to the Porto Rico deep, the gravity increased.

July 4, 21° 35' N, 63° 22' W, sea-depth 5480 metres, anomaly +0·023

" 5, 20 42 65 30 " 5290 " " +0·031

This last observation was at the edge of the deep.

July 5, 19° 30' N, 66° 51' W., sea-depth 7660 metres, anomaly −0·321,

above the deep but not at the greatest depth.

July 6, 18° 42' N, 67° 42' W, sea-depth 290 metres, anomaly +0·005,

in Mona Passage.

Before reaching Curaçao an observation was made in the Caribbean Sea.

July 6, 16° 54' N., 67° 42' W, sea-depth 4740 metres, anomaly −0·006

In the harbour of Willemstad (Curaçao) the anomaly amounted to +0·174

Between Curaçao and Colon the Caribbean Sea showed a deficiency of gravity, in the harbour of Coco Solo (Colon) the anomaly was +0·083 and in that of Balboa (Panama) +0·094

On July 31 the first two observations in the Pacific were made, but unfortunately they were both failures, the film being insufficiently extended, so that it was wrinkled and got torn. Before reaching Coco Solo there had been some difficulty in changing the speed of the film, the tension being too great, so it had been slackened. Since this experience the tension of the film has caused no further difficulty.

Along the west coast of America from Balboa to San Francisco the number of successful observations was eighteen at sea and one in the harbour of Mazatlan; so far as this harbour they showed an excess of gravity.

Aug 1, 7° 1' N., 82° 38' W., sea-depth 3020 metres, anomaly +0·061

" 3, 10 22 88 28 " 3490 " " +0·058

" 5, 13 35 95 27 " 3840 " " +0·051.

On Aug. 6 a set of four observations was made in a profile nearly perpendicular to the coast :

14° 58' N., 98° 25' W, sea-depth 3650 metres, anomaly +0·042

15 17 98 21 " 3950 " " +0·020

15 38 98 18 " 4750 " " −0·070

16 1 98 12 " 890 " " +0·037.

Aug. 8 a set of three observations :

17° 30' N., 101° 21' W., sea-depth 4990 metres, anomaly −0·076

18 0 103 26 " 3010 " " −0·070

18 14 103 27 " 670 " " +0·031.]

In the harbour of Mazatlan the anomaly was +0·036.

On July 19 a set of three observations was again made; the results have not yet been received. Along the U.S Pacific coast the gravity was normal. After leaving San Francisco a last set of three observations was made for the study of the coast effect.

In the eastern part of the Pacific the gravity was at first normal; after half the way to the Sandwich Islands had been covered it showed a positive anomaly :

Sept 14, 28° 57' N, 141° 16' W., sea-depth 4920 metres, anomaly +0·090

" 18, 22 57 153 41 " 4540 " " +0·065

It appears that the excesses of gravity in the Atlantic and the Pacific extend over enormous areas, while the excesses or defects on the continents possess a more limited, regional character.

The preliminary results of the observations do not show any trace of a flattening of the equator; it may be expected that this problem will be solved by the final results.

The long voyage from Las Palmas to Curaçao, 17 days, from San Francisco to Honolulu, 13 days, and from Honolulu to Guam, 19 days, was very strenuous, and the relaxation in the harbours was well deserved. In every harbour at which the submarine called, the crew met with the most cordial reception. Scientific workers, especially at San Francisco and at Honolulu, took much interest in Dr. Vening Meinesz and his work. In the latter place he met a number of delegates to the Pan-Pacific Congress on their voyage to Tokyo.

Thus far the voyage, the longest ever made by a submarine, has been very successful. If all goes well Dr. Vening Meinesz should have reached Surabaya about December 10; he will then stay at Java for some time to recover from the fatigues of the voyage before his return home on board a mail steamer. It may be recorded with satisfaction and thanks that the commander, the officers, and the crew of the submarine did all they could to facilitate the fulfilment of his task.

After the receipt of particulars about the rest of the voyage up to the arrival at Surabaya, I propose to give a brief account of the later results and to complete the present information.

Since the above was written, I have received from Washington the isostatic reductions of the observations made between Helder and Curaçao. These have been computed by the U S Coast and Geodetic Survey as a token of appreciation of the work of Dr. Vening Meinesz, which is justly considered to be of international interest. I must express here a word of thanks for this valuable co-operation, especially to Dr. William Bowie, Chief of the Division of Geodesy.

For the present it may suffice to mention that the excess of gravity in the Atlantic is confirmed, after the isostatic reductions have been taken into account.

The Burning of Carbonic Oxide.

IT was a sound movement on the part of the directors of the Gas Light and Coke Company to invite Prof. Bone to lecture before the Company and others on the work which he is carrying out on gaseous combustion, and particularly on the investigations made by Mr. F. R. Weston, the first holder of the Gas Research Fellowship, founded by the Company three years ago, at the Imperial College of Science. Prof. Bone had no difficulty in proving what important scientific results can be secured by means of such endowments of research, and Mr. Milne Watson, governor of the Company, showed that he realised that the development of chemical industries depended on the successful prosecution of strictly scientific investigations in the laboratory.

After comparing and contrasting the flames of hydrogen and carbonic oxide, and the effect of their mixture in water-gas, Prof Bone took up the tale of the burning of carbonic oxide as it began to be studied in Oxford fifty years ago, when H. B. Dixon, in repeating Bunsen's experiments on the distribution of oxygen between hydrogen and carbonic oxide, showed that the latter apparently did not react directly with oxygen but was oxidised by the steam, and that the final division of the oxygen depended on an equilibrium being established between this and the reverse action—the reduction of the carbon dioxide by the hydrogen:

$$CO + H_2O \rightleftarrows CO_2 + H_2.$$

The non-inflammability of dried mixtures of carbonic oxide and oxygen led to many conjectures as to its cause, and as to the mechanism of steam in the reaction. That no chemical reaction can take place without 'conducting' water; that *liquid* water particles are the necessary electrical go-between; that gases can only react molecule with molecule, *i.e.* in equal volumes, that the oxygen molecule is too stable to be broken up, but steam is more yielding—these and other explanations were advanced by men of scientific eminence. For some years Dixon has held the more prosaic view that the direct oxidation of carbonic oxide in explosions is limited by the thermal dissociation of the carbon dioxide molecules, and that steam afforded the means of producing comparative cool molecules. The burning of dry cyanogen and the direct union of carbonic oxide and oxygen in contact with heated platinum seemed to show that steam was not essential, but this and the function of the steam were matters of inference. No direct proof of what happened in the flame was forthcoming.

Prof. Bone, whose first research on gaseous combustion, carried out at the Owens College, was the study of the slow union of carbonic oxide and oxygen when circulated over heated surfaces, now brings forward direct evidence of two kinds. He shows, first, that a very well-dried mixture of the two gases, which cannot be inflamed by an ordinary spark, can be exploded (at all events partially) when the electric discharge is made sufficiently powerful. In such conditions the flame traverses the bulb containing the mixture, though not with violence, and a large percentage of the gas combines in the flame. Again, Prof. Bone and Mr. Weston have shown that as the moisture is gradually removed from the mixture, the energy of the condenser discharge required to ignite it progressively increases. Lastly, the spectra of the flames of the well-dried mixture, the moist mixture, and of mixtures containing hydrogen have been photographed. The flame of the dried mixture burning under 25 atmospheres pressure shows a *continuous* spectrum and no steam lines. The flame of the undried mixture shows a strong *continuous* spectrum overlying a '*steam-line*' spectrum. On the addition of hydrogen the continuous spectrum grows less and the lines emerge, so that there is direct evidence that two reactions are taking place simultaneously in the ordinary flame—the direct oxidation of carbonic oxide by oxygen, and the indirect oxidation by steam. The intense electric discharge, on one hand, and the high pressure on the other, can confer on carbonic oxide the power of direct union with oxygen; in the presence of much steam the indirect reaction is predominant; with traces of steam both reactions occur together.

University and Educational Intelligence.

BIRMINGHAM.—The degree of D.Sc. has been awarded to Sydney Raymond Carter for numerous published papers on the oxidising properties of sulphur dioxide and other subjects.

LEEDS.—Sir Berkeley Moynihan, Bart., has resigned the professorship of surgery on his retirement from the full staff of the Leeds General Infirmary. In recording its regret at Sir Berkeley's retirement, the Council referred to his brilliant career as student in the Yorkshire College, with which the Leeds Medical School became incorporated, and after. "Throughout his career he has followed the tradition of the Leeds Medical School in bringing scientific knowledge into the service of surgery. With this he has associated a consummate skill in the art of surgery, thereby contributing substantially to the efficacy of surgical methods and the accuracy of diagnosis."

LONDON.—A lady, who desires to remain anonymous, has offered the University the sum of 10,000*l.* towards the establishment of a chair of dietetics.

Subject to certain conditions, the offer of Mr. J. G. Wilson to present to the University a 24-inch reflector telescope has been accepted. Lady Godlee is giving a sum of money, to be held in trust for University College and University College Hospital Medical School, to found a Rickman Godlee Lectureship in memory of her husband, the late Sir Rickman J. Godlee. The managing director of the Vultex Products, Ltd., on behalf of Mr. Patrick Gow, is to give a sum of money for three years for lectures on colloidal chemistry.

The following doctorates have been conferred:—*D.Sc. in Botany* on Mr. T. G. Hill, University reader in plant physiology, for a thesis entitled "The Water Economy of Maritime Plants"; *D.Sc. in Physics* on Mr. S. C. Roy (King's College), for a thesis entitled "On the Total Photo-electric Emission of Electrons from Metals as a Function of Temperature of the Exciting Radiation"; *D.Sc.* (*Engineering*) on Mr. L. B. Pfeil (Imperial College, Royal School of Mines, and Battersea Polytechnic), for a thesis entitled, (1) "The Deformation of Iron, with particular reference to Single Crystals;" and (2) "The Effect of Cold Work on the Structure and Hardness of Single Iron Crystals, etc."; *D.Sc. in Chemistry* on Mr. T. H. Durrans, for a thesis entitled "The Preparation of Sulphuryl Chloride and the Chlorination of Substances of the Aromatic Series"; together with subsidiary contributions.

Dr. Percival Hartley has been awarded the William Julius Mickle Fellowship for 1927 in respect of the work which he has carried out during the past five years on special problems in connexion with diphtheria and other problems of a more general character in connexion with serology and immunity. The Fellowship this year is of the value of about 280*l*.

THE Educational Commissioner with the Government of India in his Report for 1924–25 gives a new and very convenient summary of statistics showing totals of 88,750 students, 5700 teachers and 7500 graduations in arts and science of the fifteen universities. 52 per cent. of the students, 50 per cent. of the teachers, and 48 per cent. of the graduations belonged to the two universities of Calcutta and Madras; Bombay and the Panjab account for 25 per cent. of the students, 21 per cent. of the teachers, and 20 per cent. of the graduations; leaving 29 per cent., 23 per cent. and 32 per cent respectively as the share of the remaining eleven universities. These eleven, namely, the recently reconstituted Allahabad University and the ten new universities of Aligarh, Benares, Dacca, Delhi, Hyderabad (Osmania University), Lucknow, Mysore, Nagpur, Patna, Rangoon, had in the aggregate not much more than two-thirds of the number of students of the single university at Calcutta. An act, constituting a new "Andhra" university was passed in 1926. Every one of the universities had a faculty of arts; all except the Osmania University of Hyderabad (Deccan) had a faculty of science; all except Aligarh and Mysore a faculty of law; all except Aligarh, Allahabad, Benares, Dacca, Delhi, Nagpur, and Osmania, a faculty of medicine. There were faculties of education at Aligarh, Madras, Nagpur, Patna, and Rangoon; of theology at Aligarh, Benares, and the Osmania University; of agriculture at Madras and the Panjab; of forestry at Rangoon; of engineering at Calcutta, Madras, Mysore, Patna, and Rangoon; of economics at Allahabad and Rangoon; of commerce at Allahabad, Lucknow, and the Panjab. The total expenditure on universities, arts colleges, professional colleges, and intermediate colleges in India in 1924–25 was Rs. 83,76,000, Rs. 1,06,28,000, Rs. 65,16,000, and Rs. 28,00,000 respectively; in all Rs. 2,83,20,000 or, say, 2,124,000*l*. The sources from which the expenditure was met were: Government funds Rs. 1,43,29,000, district board and municipal funds Rs. 76,000, fees Rs. 1,08,43,000, other sources Rs. 30,73,000. Universities, notably Bombay and Calcutta, have received in recent years substantial additions to their resources through the generosity of private donors, but it will be seen that they are in the main dependent on Government funds and fees.

Contemporary Birthdays.

December 26, 1838.	Sir W. Boyd Dawkins, F.R.S.
December 26, 1881.	Sir Thomas Lewis, F.R.S.
December 28, 1882.	Prof. A. S. Eddington, F.R.S.
December 28, 1853.	Dr. Alexander Scott, F.R.S.
December 30, 1850.	Dr. William Garnett.
December 31, 1849.	Prof. Sydney H. Vines, F.R.S.

Sir WILLIAM BOYD DAWKINS, honorary professor of geology and palæontology in the University of Manchester, celebrates his eighty-eighth birthday to-morrow. We offer our very hearty congratulations. A fellow of the Geological Society for sixty-five years, he will, next year, attain diamond jubilee fellowship of the Royal Society. He is the author of two classical works, "Cave Hunting" and "Early Man in Britain."

Sir THOMAS LEWIS, born at Cardiff, was educated at Clifton College; his medical training was conducted at University College Hospital, London. Eminent in long-continued developmental studies relating to the mechanism and clinical disorders of the mammalian heart-beat, he has established conclusions of prime importance in physiology and practical medicine. Sir Thomas was Croonian lecturer at the Royal Society in 1917, delivering an address on "The Excitation Wave in the Heart."

Prof. EDDINGTON was born at Kendal. A student at Owens College, Manchester, he graduated at Trinity College, Cambridge, as senior wrangler, and was Smith prizeman. He was chief assistant at the Royal Observatory, Greenwich, from 1906 until 1913, leaving this post to become Plumian professor of astronomy in the University of Cambridge. Prof. Eddington was president of the Royal Astronomical Society, 1921–23; in 1924 he received its gold medal for his work on star-streaming, on the internal constitution of a star, and on generalised relativity. In the same year he was awarded the Henry Draper medal of the National Academy of Sciences of the United States.

Dr. A. SCOTT, a native of Selkirk, and educated there at the Grammar School, graduated at the University of Edinburgh, and also at Trinity College, Cambridge. From 1896 until 1911 he was superintendent of the Davy-Faraday Research Laboratory, Royal Institution. Dr. Scott was president of the Chemical Society, 1915–17, after many years of service to the Society in various administrative capacities.

Dr. GARNETT, born at Portsea, was educated at the City of London School and Royal School of Mines. Proceeding to St. John's College, Cambridge, he graduated fifth wrangler, becoming later a fellow of his college. Entering the Cavendish Laboratory, he had the distinction of being the first demonstrator of physics there under James Clerk Maxwell. After teaching at University College, Nottingham, he did valuable work as principal of the Durham College of Science. The advancement of technical education in London and elsewhere claimed earnest attention at his hands; from 1904 until 1915 he was educational adviser to the London County Council. Dr. Garnett is Hon. D.C.L., Durham.

Prof. VINES, distinguished as a botanist, is a Londoner. Educated privately, he graduated at Christ's College, Cambridge. For many years he was Sherardian professor of botany in the University of Oxford. He was president of Section K (Botany) at the Bradford meeting of the British Association in 1900, when he gave, in his address, a conspectus of botany in the nineteenth century. Prof. Vines was president of the Linnean Society, 1900–4.

Societies and Academies.

LONDON.

Geological Society, November 17.—C. J. **Stubblefield** and O. M. B. **Bulman**: The Shineton shales of the Wrekin district, with notes on their development in other parts of Shropshire and Herefordshire. In the Wrekin district, the Shineton shales represent almost the whole of the Tremadocian succession, as developed in the Tremadoc district. The subdivision of shales in this main outcrop are:—(6) Arenaceous beds; (5) zone of *Shumardia pusilla*; (4) Brachiopod beds; (3) zone of *Clonograptus tenellus*; (2) transition beds; (1) zone of *Dictyonema flabelliforme* In the smaller outcrops of the shales lying on the west and south-west, only the lower part of the sequence has been identified. In the Wrekin district a thick mass of shales has been compressed against a north-eastern ridge formed of earlier Cambrian and pre-Cambrian strata, resulting in isoclinal folding with faulting in the north-eastern part of the shale outcrop. In the south-west of the district the shales are less disturbed, except in the immediate neighbourhood of the Church Stretton fault. Six new species of trilobites have been established, of which three belong to new genera; one new brachiopod and three new hyolithids are described.—W. J. **Arkell**: The Corallian rocks of Oxfordshire, Berkshire, and North Wiltshire. The subdivisions adopted are: (5) upper Calcareous grit; (4) *Trigonia-clavellata* beds; (3) Osmington Oolite series; (2) Berkshire Oolite series; (1) lower Calcareous grit. It is particularly emphasised that the Coral Rag is a facies deposit which may occur at any date, and that the use of 'the Coral Rag' as a stratigraphical term is not permissible. The substitution of the term by Blake and Hudleston's 'Osmington Oolite Series,' is suggested. Coral associations started in Yorkshire at the time of the lower Calcareous grit, and migrated southwards during the Corallian epoch, failing to become established in Dorset until the closing phase of the upper Calcareous grit. The chief feature of the Berkshire Oolite series, the Trigonia beds of Berkshire, are contrasted with the much later Trigonia beds of Dorset; whereas the former belong to the Argovian, the latter must be assigned to the Sequanian, the intervening Osmington Oolite series undoubtedly representing the Rauracian.

Linnean Society, November 18.—Miss E. R **Saunders**: The origin of the double garden stock A plant which appeared in the present season in an F_2 family from the cross, pure-breeding glabrous single cream ♀ × double-throwing glabrous white ♂, is of considerable interest, for the normal single and fully double condition were here exhibited in the same individual. The cross was made in 1923 and the resulting seeds sown the same autumn. The F_1 plants, which were purple and hoary (the factorial constitution of the parents being RHK and CK respectively), flowered in 1924. The seeds collected from one of these plants, which was covered, were not sown until the spring of 1926, when they yielded 179 hoary and 100 glabrous, of which 214 were single and 58 double. One of the hoary single-flowered plants produced six primary lateral axes in addition to the main axis; some of the flowers on the main axis showed characters intermediate between those of the single and those of the double flower. The sixth lateral branch produced mainly double flowers indistinguishable from those borne by the ordinary double-flowered plant. It is therefore possible that the mutation occurring here in only one branch may at some time have occurred throughout a whole individual, and so have given rise at one step to the double-flowered type.—Miss A. E. **Chesters**: The vascular supply of the bracts of some species of Anemone. In types exhibiting a large leafy involucre the vascular system of the peduncle is dominated by that of the involucre. In species like *A. Hepatica*, in which the involucre closely approximates to a calyx, the incoming bundles take a less prominent part in the formation of the vascular ring of the axis. The resemblance between the course of the bract bundles of *A. Hepatica* and the sepal bundles of *Ranunculus Ficaria* is very striking. The vascular supply of the bracts of *Eranthis hyemalis* resembles that of *A. nemorosa* in all essentials, suggesting that the modifications shown in the vascular system of *A. Hepatica* and *A. angulosa* are correlated with the reduction of the involucral leaves rather than with the difference in position. The evidence appears to support the view of the homology of the involucre of *A. Hepatica* and the calyx of *Ranunculus Ficaria*.

Physical Society, November 26.—H. C. **Hepburn**: Electro-endosmosis and electrolytic water transport. Determinations were made of liquid transport produced by passing an electric current through aqueous solutions of copper sulphate divided perpendicular to the flow of electricity by a diaphragm of powdered glass. The probable factors that determine the liquid transport are investigated over a wide range of concentrations, by an examination of the dependence of the flow at constant applied voltage and of the electric charge of the diaphragm on the electrolyte concentration, and also by a study of the relation between the flow per faraday and the dilution of the electrolyte.—L **Hartshorn**: The input impedances of thermionic valves at low frequencies. Accurate measurements of input admittance (or of input impedance) under various conditions can be made by means of the Schering capacity bridge. The input circuit is regarded as being equivalent to a condenser with a definite phase angle, ϕ, or "loss angle," $\delta = 90° - \phi$, and the results are expressed by stating the effective capacity and value of tan δ for each set of experimental conditions The effective capacity may vary from about 10$\mu\mu$F. to 100$\mu\mu$F. for an *R* valve, and the phase angle may vary from about 80° leading to 126° leading, depending mainly on the load in the anode circuit. Values of phase angle greater than 90° correspond to a negative resistance or negative power factor, and occur when the load in the anode circuit is inductive.

CAPETOWN.

Royal Society of South Africa, September 29.—T. R. **Sim**: The Bryophyta of South Africa.—E. Percy **Phillips**: Some notes on South African grasses. The characters and distribution of the various South African grasses, and the economic questions associated with them are discussed, and the effects of veld burning described.—J. H. **Power**: Some tadpoles from Griqualand West.

October 20.—John **Phillips**: Faurea McNaughtonii Phill. ("Terblanz"), a note on its ecology and distribution. This stately forest tree (Proteaceæ: sect. Persoonioideæ) is of peculiar regional and local distribution.—M. R. **Levyns**: Note on the genus Lobostemon (Lehm.) A new classification, based on floral characters, is used. It is proposed to restrict the genus Lobostemon to those forms in which a definite scale or swelling is present on the corolla at the base of each stamen, and to constitute a new genus for those forms in which a scale or swelling is absent.—**P. R. v. d. R. Copeman**: Studies in the growth of grapes. Equations have been developed for the growth changes in the acid, sugar, and soluble solid content of the juice and in the total solids in the berry for six different varieties of grapes analysed during three seasons. The growth of the grape berry may be divided into two distinct cycles. In the first cycle the soluble solids formed consist mainly of acid and protein. During the second cycle the changes in the soluble solids are practically entirely due to the changes in the sugar and acid. Growth constants can be derived which serve as a means of comparison between the different varieties for the different seasons.—**H. O. Monnig**: On a new Physaloptera from an eagle and a Trichostrongyle from the cane rat, with notes on *Polydelphis quadricornis* and the genus Spirostrongylus.—**D. F. Bleek**: Bushmen of Central Angola. These Bushmen are Kung, speaking a language similar to the like-named inhabitants of the South-West Protectorate. They are much influenced by the surrounding Bantu tribes, on whom they are becoming more and more dependent. Their religious beliefs are akin to those of other Bushmen, save for an acquired fetish worship. The tribe will probably be absorbed by the Bantu races.

ROME.

Royal National Academy of the Lincei, Communications received during the vacation.—**U. Cisotti**: Inversion of Poisson's formula on rigid motions.—Giorgio **Abetti**: Observations on the motions of metallic vapours in sunspots.—**L. A. Herrera**: Chemotaxis and phagocytosis in imitation of leucocytes. The microscopic amœba-like forms produced in petrol and olive oil by the injection of drops of alkaline water are due to currents and movements produced by rapid penetration into the osmotic pockets of the oil rendered more fluid by the petrol. The results indicate that phagocytosis must be regarded as of mechanico-physico-chemical character. Acetic acid acts as an anti-body or opsonin which determines the chemotaxis of the oily 'amœbæ.' It seems probable that similar currents are produced between the natural leucocytes and bacteria.—Tommaso **Boggio**: The geodetic deficit.—**E. Bompiani**: The geometry of surfaces considered in ruled space.—Alessandro **Terracini**: The linear projective element of a surface.—**E. Raimondi**: General formulæ for the calculation of the dynamic effect of a current flowing between a strip and an indefinite plane wall.—Renato **Mancinelli**: The Evershed effect in sunspots.—Mario **Picotti**: Results of the physico-chemical investigations made in the Italian cruiser *Marsigli* in the Straits of Messina. The amount of oxygen dissolved in the water of the Straits of Messina rises to maximum values in April and in September, in which months plankton are exceptionally plentiful. The value of pH lies mostly between 8·1 and 8·2, but values below 8·1 are sometimes encountered in the depths and values above 8·25 at the surface.—Marya **Kahanowicz**: Spectrum of the Pickering type in argon. Under a suitable pressure and when strongly excited, argon gives rise to an enhanced spectrum of the Pickering type. The emissive atom exhibits hydrogenoid behaviour, an electron revolving about the nucleus.—**G. Wataghin**: The aberration of light and the theory of relativity. The relativistic formula for aberration, established by Einstein for plane-waves, is valid also for spherical waves. The theory of aberration may be developed on the basis merely of the hypothesis that light is propagated in a straight line with respect to any inertial system whatever. Various particular aspects of the theory are discussed.—Bianca **Nannei**: Method for the measurement of variations in the calorific capacity in magnetic fields.—Marcelle **Philibert**: Apparent doubling of the optic axis of calcite with Federow's plate.—**G. Carobbi**: Investigations on some noteworthy Vesuvian sublimates. The presence of traces of soluble vanadium compounds is observed for the first time, and that of soluble titanium compounds and boric acid confirmed, in deposits on Vesuvius.—Gaetano **Charrier**: 1-*N*-Phenyl-αβ-naphtho-1:2:3-triazolequinone.—Raoul **Poggi** and Angiolo **Polverini**: The determination of phosphorus and arsenic in organic substances. The method suggested consists in oxidising the substance by means of concentrated sulphuric acid and potassium persulphate, and afterwards determining the phosphorus or arsenic by the ordinary methods.—**G. Scagliarini** and **G. Tartarini**: Compounds of titanium halides with oxygenated organic substances.—Edoardo **Benedetti**: The action of the high frequency oscillating electromagnetic field on vegetable seeds. Experiments made with maize, wheat, barley, and rice show that the oscillating field results in both accelerated growth and increased percentage germination.—Umberto **D'Ancona**: The reproduction of *Alosa finta* (Cuv.).

SYDNEY.

Royal Society of New South Wales, October 6.—**A. R. Penfold** and **R. Grant**: The germicidal values of some Australian essential oils and their pure constituents; together with those of some essential oil isolates, and synthetics (Part 4). The Rideal-Walker co-efficients of some Australian essential oils and perfume synthetics have been determined. The following coefficients were measured: Western Australian sandalwood oil, 1·5; East Indian sandalwood oil, 1·5; *Zieria macrophylla*, 2·0; zierone, 2; isomenthol, 20; phloracetophenone-dimethyl-ether, 10; hydrocinnamic-aldehyde, 7 (5·3); hydroxycitronellal, 6 (4); C_8 aldehyde, 16 (22); C_9 aldehyde, 9·5 (23); C_{10} aldehyde, 7 (9·25); C_{11} aldehyde, 7 (9·25); C_{12} aldehyde (methylnonyl acetic), 1 (3·5); C_{12} aldehyde (laurinic), 3 (5); C_8 alcohol, 25 (26), C_9 alcohol, 13 (19); C_{10} alcohol, 5 (6·25); C_{11} alcohol, 4·5 (5·75); C_{12} alcohol, 2·75 (3·5). The dispersions consisted of 1 per cent. of the constituents in 7·5 per cent rosin-soap solution. The numerals in brackets refer to the dispersions in absolute ethyl alcohol.

Thursday, January 6, at 9.45 A.M.—F. Twyman: Spectrum Analysis by Emission Spectra.—E. J. Holmyard: Alchemy.—N. V. Sidgwick: Atomic Structure and the Periodic Law.—At 5.15.—R. S. Capon: Aeroplane Performance Testing.—At 8.15.—Prof. H. H. Turner: Eclipses, with special reference to the Total Eclipse of June 29, 1927.

Friday, January 7, at 9.45 A.M.—G. M. B. Dobson: The Upper Atmosphere.

Supplement to NATURE

No. 2957 JULY 3, 1926

Some New Possibilities in Solar Research.

By Dr. GEORGE E. HALE, For. Mem. R.S.

FORTY years ago I began a series of visual and photographic studies of the sun. Recently I have returned to this work, after an interval of enforced absence. My instrumental equipment is now augmented by the addition of a spectrohelioscope, a simple device for monochromatic vision which we owe in its essence to the pioneers of solar research. This renders visible a host of important phenomena hitherto concealed from view by the overpowering brilliancy of the sun's disc. Chief among these are the radiating and absorbing regions of the hydrogen atmosphere, visible with the spectroscope in profile at the sun's limb, and revealed in projection by spectroheliograms of the disc, but now accessible, wherever they may be situated, to visual observation with instruments of moderate size.

All readers of NATURE who are familiar with its early volumes will remember the discoveries of Janssen and Lockyer in 1868. At the total solar eclipse of that year, Janssen, who was observing in India, was so impressed by the brilliancy of the lines in the spectrum of the prominences that he determined to look for them in full sunlight. He did so, and was at o[illegible]ded. The bright light of the sky around th[illegible] which ordinarily hides the prominences from us, gives the spectrum of scattered sunlight. Entering the spectroscope through a slit from one to three-thousandths of an inch wide, it is spread out into a band from a few inches to forty feet in length, depending upon the dispersive power of the spectroscope. Its intensity may thus be reduced indefinitely. The bright lines of the gaseous prominences, however, are essentially monochromatic. High dispersion separates them more and more widely, without greatly weakening them. They thus become readily visible on a fainter background of dispersed skylight. The principle involved was first stated by Lockyer in 1866 and successfully tested by him in 1868, before the news of Janssen's discovery had reached Europe. This application of the spectroscope opened a new and productive era in solar physics, enlisting the active efforts of astronomers in England, France, Italy, Germany, and the United States.

Naturally these observers wished to see not merely the spectra of the prominences, but also their forms. In his well-known book, "Contributions to Solar Physics" (p. 578), Lockyer describes how the first steps were taken:

> "In my first paper I gave some drawings procured by causing the slit to pass slowly over the prominence. By this means a number of sections of varying length was obtained, which, placed side by side, gave an idea of its shape The slit then used was extremely narrow, and was radial to the sun's limb. It was obvious that in this way the true shape of the prominence could not be seen unless the slit were moved with sufficient rapidity to allow of persistent images. At the very outset Janssen and myself attempted to accomplish this, Janssen by giving a rotatory motion to a direct vision spectroscope, I by giving an oscillating motion to the slit, in which I was followed by Young, who afterwards expanded it."

Prof. Young's account of his instrument is as follows:

> "The eye-piece of the instrument has an apparatus attached, which, however, thanks to the high dispersive power, I find unnecessary.
>
> "It was early proposed by Janssen to use a vibrating or rotating slit in order to make visible the form of a solar prominence, but as Zollner has shown, the mere opening of the slit answers just as well, the light of the protuberance being diluted to precisely the same extent in either case.
>
> "It occurred to me in connexion with a suggestion of Professor Morton, that by interposing at the focus of the eye-piece a diaphragm which should move with the vibrating slit, the light of the neighbouring portions of the spectrum might be cut off and this dilution avoided. Mr. Clark has devised and constructed a very beautiful mechanical arrangement by which this simultaneous and accordant motion of slit and diaphragm is effected by the rotation of the small fly-wheel shown in Fig. 1.
>
> "But I find, that although seen in this way, the prominences appear very bright; yet the working of the apparatus always causes a slight oscillation of the equatorial, which interferes with the definition of details, and I prefer to work with the slit simply opened." (Young, NATURE, Dec. 8, 1870.)

The introduction by Zollner and Huggins of the wide slit method and the superb views it afforded of the prominences at the limb led to its universal adoption, and the oscillating slit was abandoned. Although Lockyer and Young often examined the spectra of sun-spots and other regions of the photosphere, and repeatedly described reversals and distortions of hydrogen and other lines, I can find no indication that the oscillating slit device was ever tested for the observation of the forms of eruptions or other phenomena on the disc. Nevertheless, the credit for building the first spectrohelioscope (as I have named the instrument) and applying it to the observation of prominences at the limb belongs to my old friend Prof. Young, who was also the first to take photographs of the forms of the prominences through an open slit (*loc. cit.*).

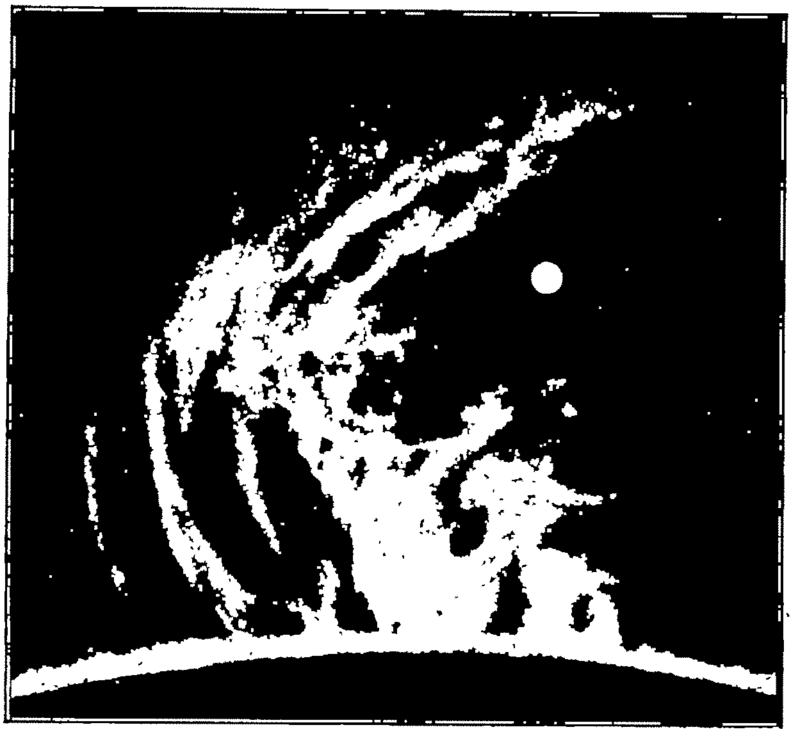

Fig. 1.—Active prominence, 140,000 miles high, photographed by Ellerman at Mount Wilson, July 9, 1917, with the *K* line of calcium. The small disc represents the comparative size of the earth.

THE SPECTROHELIOGRAPH.

The principle of the spectroheliograph, which does not differ greatly from that of Young's instrument with oscillating slit, occurred to me in 1889.[1] It involves the use of a spectroscope with a fixed second slit, through which a single line is admitted to a photographic plate. The whole spectroscope is mounted on steel balls, and moved slowly by a motor across the solar image, which, like the photographic plate, remains stationary. Or the spectroscope may be fixed in position, and the solar image and plate moved at the same speed across the first and second slits respectively. A monochromatic image of the sun is thus gradually built up on the plate from countless successive images of the narrow second slit.

After some preliminary experiments at the Harvard Observatory, I obtained photographs of prominences with a simple spectroheliograph at the Kenwood Observatory in the spring of 1891. In January 1892, with an improved spectroheliograph, I succeeded in photographing the chromosphere and prominences (Fig. 1) surrounding the sun and the bright flocculi[2] revealed on the disc by the use of the *H* or *K* line of calcium.

About this time Deslandres introduced the velocity spectrograph for photographing the *H* or *K* line in successive sections of the sun. Evershed soon constructed and systematically employed a spectroheliograph, and in 1893 Deslandres also began work with a spectroheliograph, which he employed for photography with the calcium lines and with some of the narrower dark lines. In 1903, with the Rumford spectroheliograph attached to the 40-inch refractor of the Yerkes Observatory, Ellerman and I first photographed the bright and dark hydrogen flocculi on the disc and noted especially the long dark flocculi (Fig. 2) identified as prominences projected against the sun (named 'filaments' by Deslandres, who has studied them extensively at Meudon with the spectroheliograph and velocity spectrograph). Five years later, at Mount Wilson, aided by plates sensitised for photography in the red, Ellerman and I discovered large vortices surrounding sunspots (Figs. 3 and 10). The Hα line, with which the vortices were found, is much more

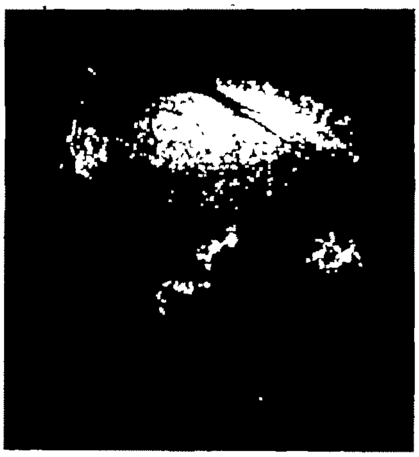

Fig. 2.—Hydrogen (*H*α) flocculi, photographed with the 13-foot spectroheliograph at Mount Wilson, February 17, 1926, at $10^h\ 00^m$. All of these could be seen in Pasadena with the spectrohelioscope

effective than the more refrangible hydrogen lines for the study of the hydrogen atmosphere of the sun Its situation in the red also adapts it for visual observations, particularly at low altitude stations where smoke and haze may seriously interfere with work at the violet end of the spectrum. With a spectroheliograph of high dipsersion, *Hα* shows also the 'alignments' discovered by Deslandres, which constitute a reticular structure of wide mesh associated with the filaments.

---

[1] I afterwards found that it had been first suggested by Janssen, embodied in a practicable design by Braun (not constructed), and unsuccessfully tested by Lohse.

[2] Flocculi is a general term applying to all markings, bright or dark (excepting sunspots), photographed by the spectroheliograph on the sun's disc.

The spectroheliograph, in addition to providing a method of photographing the chromosphere and prominences, at the sun's limb, has thus made possible the daily study of the solar atmosphere in projection against the disc. But useful as it has proved, the need for a similar means of visual observation has persisted for many years.

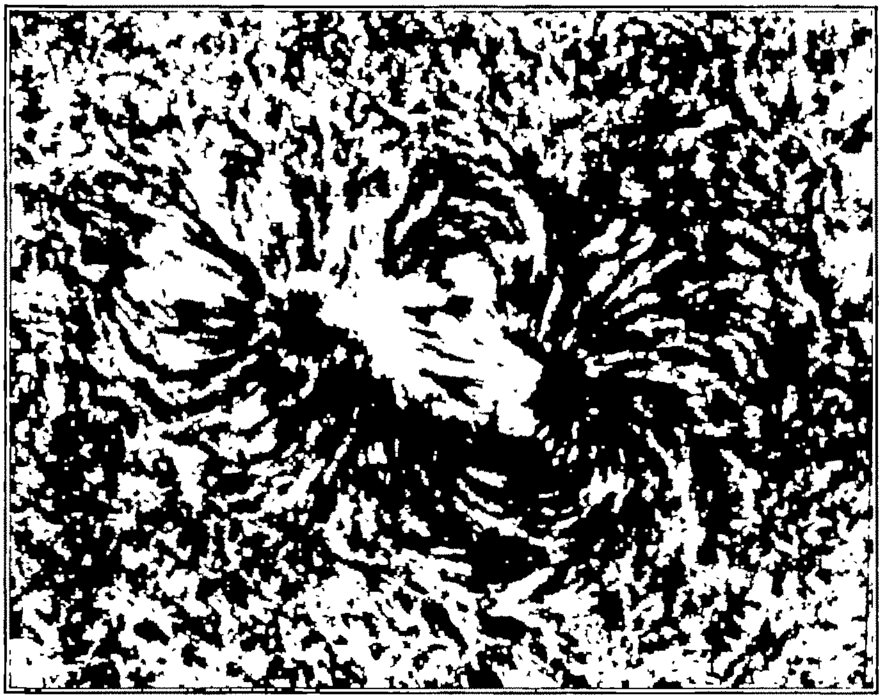

Fig. 3 —Hydrogen (*Hα*) vortices surrounding the bipolar sunspot of September 1924, photographed by Lewis Humason at Mount Wilson with the 13-foot spectroheliograph.

THE SPECTROHELIOSCOPE.

My first attempts to observe the hydrogen flocculi visually were made on Mount Wilson with the 60-foot tower telescope and 30-foot spectroheliograph soon after the discovery of the *Hα* vortices in 1908 A disc carrying a large number of radial slits was mounted just above the wide first and second slits on a vertical bearing standing midway between them. Each of these radial slits, when near the axis of the collimator, thus produced a spectrum, and by adjusting the grating (or prism) the *Hα* line could be brought into coincidence with the corresponding slit on the opposite end of the same diameter. A given displacement of the first slit produced an equal displacement of the *Hα* line in the opposite direction. Thus, when the disc was rotating, the observer, looking through a positive eye-piece focussed on the slits coinciding with the *Hα* line, saw an image of a portion of the sun in hydrogen light. Unfortunately, the slits were too wide and too few in number, and for many years I had no opportunity to bring the method into effective form

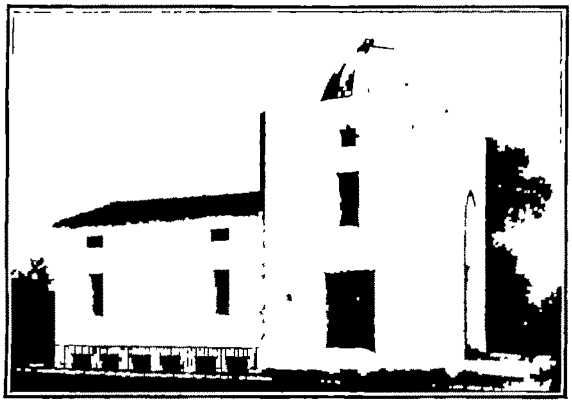

Fig 4 —Solar Laboratory in Pasadena The second mirror of a coelostat beneath the dome sends parallel rays vertically downward to a 12-inch objective, giving a 2-inch solar image on the slit of the spectrohelioscope in the basement By a simple change, a Cassegrain reflector of 18 inches aperture, giving a solar image either 6¼ inches or 16¼ inches in diameter, can be substituted for this objective

In 1923 I renewed the effort, with results which have been described in these pages (NATURE, October 25, 1924, p 628). At that time, however, the apparatus was crudely mounted, and its consequent inefficiency, at a period of low solar activity, gave me no measure of its actual powers. Recently the same optical parts, now adequately mounted in my new Solar Laboratory in Pasadena (a branch of the Mount Wilson Observatory), have yielded results of greater interest

A very brief description of the instrument will suffice. Imagine a reflecting spectroscope of 6 inches aperture and 13 feet focal length, standing vertically in a well beneath the laboratory (Fig. 5). A solar image 2 inches in diameter is formed on the slit by a 12-inch objective.

A cœlostat, with second mirror, mounted beneath a dome at the summit of a low tower (Fig. 4) sends parallel rays of sunlight vertically downward to the 12-inch objective, which stands 18 feet (its focal length) above the slit. Electric slow motions, controlled by buttons within easy reach of the observer, permit the objective to be focussed and the solar image to be moved in any direction across the slit. Thus all parts of the limb or disc can be examined in quick succession.

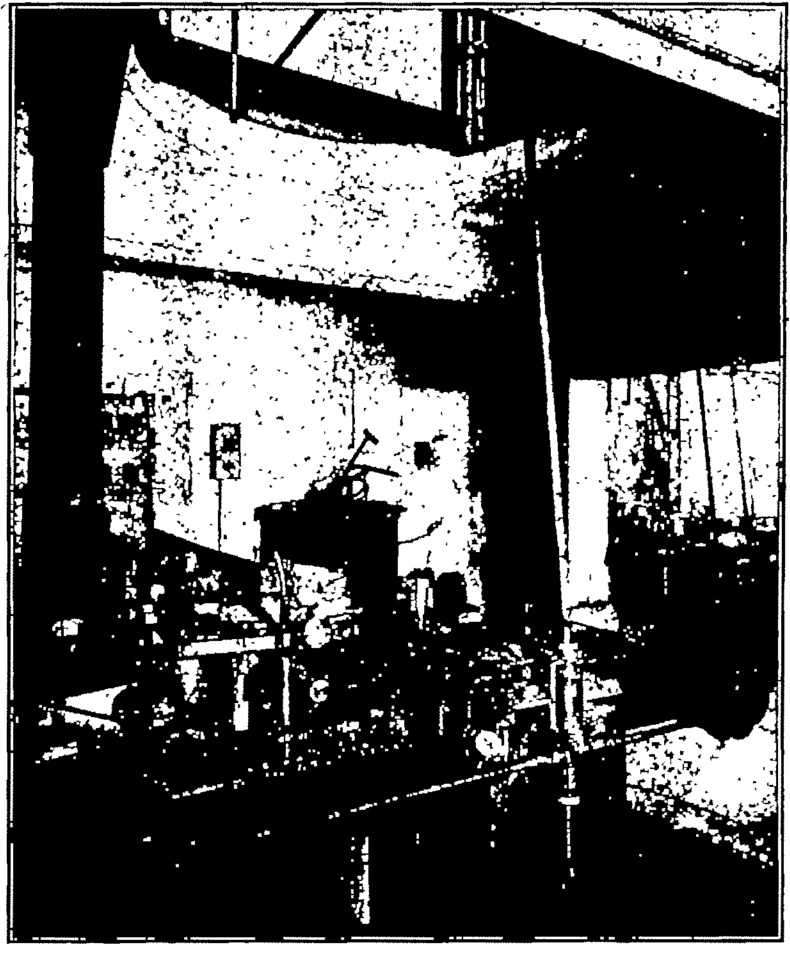

Fig. 5.—Upper end of combined spectrohelioscope, spectrograph, and spectroheliograph, mounted vertically in a well 10 feet in diameter and about 80 feet deep. The oscillating slit-bar and binocular eye-piece may be seen near the middle of the instrument. These are ordinarily employed with a reflecting spectroscope of 13 feet focal length, also designed for use as a spectroheliograph. By turning its optical parts out of the way, the instrument is transformed into a Littrow spectrograph of 75 feet focal length, suitable for researches on the magnetic fields in sunspots.

The second slit lies in the plane of the spectrum, formed by a large plane grating, ruled by Jacomini on the ruling machine of the Mount Wilson Observatory. The first order spectrum, which is very bright, is usually employed. The *Hα* line is brought into coincidence with the second slit, which is narrower than the (dark) line. The slits are carried at opposite ends of a horizontal bar, which can be oscillated (usually through a range of a quarter of an inch) about a bearing half-way between them (Fig. 6). As the optical arrangements are such that the second slit constantly bisects the oscillating *Hα* line, a monochromatic window, one-quarter of an inch wide, is thus provided through which to view the sun. A positive eye-piece magnifying about 2·5 diameters, mounted on the binocular body of my Spencer microscope, is used for observing the hydrogen atmosphere through this window. The speed of the driving motor is fast enough to give a persistent image. As the (visible) length of the window thus employed is about half an inch, a considerable portion of the 2-inch solar image can be seen at once.

I was agreeably surprised when I first tried this apparatus on January 16 of the present year. I knew from previous experience that the prominences at the limb and the more conspicuous dark and bright flocculi on the disc would be visible, but I was scarcely prepared for the delicate details of structure, both dark and bright, which appeared in good contrast on the disc. At that time (as in the earlier work) I was using five slits at each end of the bar, instead of one. These were only one-twelfth of an inch apart, restricting the field of view to this width. The central image in the eye-piece, corresponding to the $H\alpha$ line, was flanked on either side by brighter images of the same region,

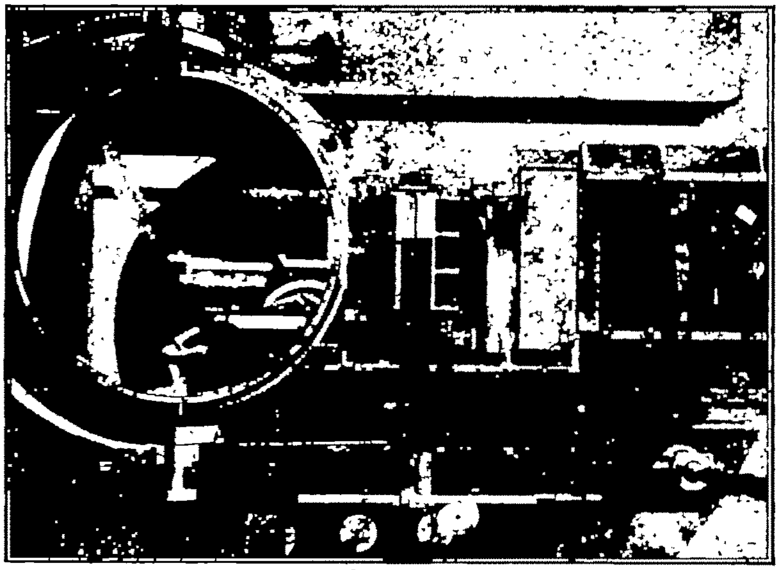

FIG. 6.—Plan of spectrohelioscope. The oscillating slit-bar, mounted on a bearing movable by the micrometer screw near the centre of the photograph, is driven by a motor at the left (shown in Fig. 5). The observer looks through the binocular eye-piece, which is focussed on the second slit. The 18-inch concave mirror of the Cassegrain reflector, the driving mechanism and sliding plate-holders of the spectroheliographs, and the buttons for electric control, may also be seen in the photograph.

formed by the light of the continuous spectrum. Thus, in examining a spot region the hydrogen flocculi above and about the spots could be seen in the central image while the underlying spots and photosphere appeared in the side images—a convenient means of comparison. Frequently in the hydrogen image the spots are entirely concealed by flocculi, and in tracing the spiral structure in a vortex to its objective, it is advantageous to be able to see the spots simultaneously. For this and other reasons two or more second slits may sometimes be preferred to one. By means of a special device, however, similar comparisons can be easily made with only one second slit.

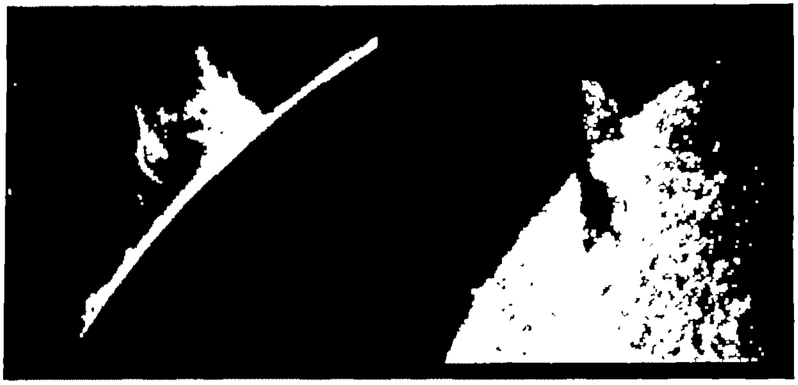

FIG. 7.—Solar prominence partly projected upon the disc, photographed by Ellerman at Mount Wilson with the 15-foot spectroheliograph (using $H\alpha$) May 22, 1916. At the left is a longer exposure of the same prominence, made with the disc covered.

EXPLORING THE SOLAR ATMOSPHERE.

As a quick and effective means of exploring the entire solar atmosphere the spectrohelioscope is unrivalled. In a few minutes one may run completely around the limb, not only observing the chromosphere and prominences projecting beyond it, but also following with equal ease those which extend on to the disc and appear there as dark absorbing masses. Such a prominence, from a spectroheliogram taken some years ago by Ellerman on Mount Wilson, is illustrated in Fig. 7. It will presently appear why objects of this nature can often be better seen with the spectrohelioscope than they can be photographed with the spectroheliograph.

The utility of the spectrohelioscope as a scouting auxiliary of the spectrograph or spectroheliograph is thus apparent. Hitherto the observer with these instruments has often worked blindly, not knowing in advance what phenomena of the solar atmosphere lie between him and the visible structure of the photosphere. A few minutes of visual observation may now enable him to select interesting regions for special study, or to avoid areas where eruptions, vortices, or other active phenomena may interfere with measurements requiring a more normal state of tranquillity. Such selections can also be made with the spectroheliograph, but far less quickly and effectively. The fact that very different phenomena are observed when the second slit is set on different parts of the $H\alpha$ line is a vital factor here.

EFFECTS OF LEVEL AND OF RADIAL MOTION.

In our early work with the spectroheliograph, M. Deslandres and I independently utilised the principle of photographing cross-sections of the calcium flocculi at different levels by setting the second slit in successive exposures at various distances from the centres of the H and K lines. As these lines widen in descending through the calcium atmosphere toward the photosphere, it is obvious that if the second slit is set at a given distance from the centre, none of the higher calcium vapour, which gives a narrower line, can be included in the photograph. Similar work was afterwards undertaken with the hydrogen lines, where the velocity of the gas in the line of sight is often of greater significance than its level.

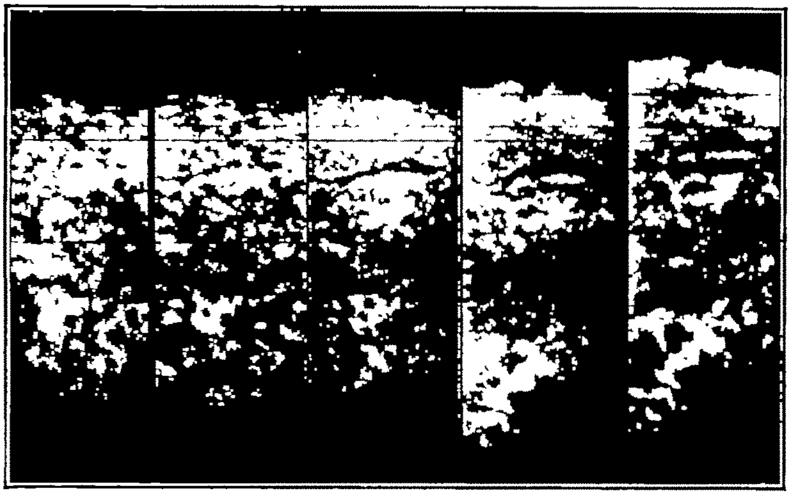

FIG. 8.—Five exposures by Ellerman with the 13-foot spectroheliograph, showing the changes in the flocculi corresponding to second-slit position, ranging from λ6564·36 (left) to the centre of $H\alpha$ (May 29, 1916)

Fig. 8 illustrates the different appearances of a given region of the solar atmosphere when photographed with the second slit at various distances from the centre of $H\alpha$. Many studies of this kind have been made at Mount Wilson, and these have been supplemented by other investigations based upon photographs taken with a single first slit, an optical system giving two spectra of the same region of the sun, and two second slits, one set on the red side of $H\alpha$ in one spectrum, the other on its violet side in the second spectrum, equidistant from the centre of the line. Two photographs of the same region of the hydrogen atmosphere thus obtained simultaneously often show remarkable differences, as Fig. 9 illustrates. In this picture of an active spot region the bright eruptive flocculi appear in both photographs, because the corresponding bright $H\alpha$ line was wide enough to overlap both of the second slits. The dark flocculi, produced by the cooler gas at a much higher level, gave a narrower line, displaced to the red because of the rapid descent of this gas. The structure of this rapidly falling gas is consequently shown only in the lower photograph, made with the second slit set on the red side of the line.

The power of the spectroheliograph thus to single out gaseous masses moving rapidly in the line of sight is one of its most valuable properties. This effect can be minimised, if it is desired to record on a single plate all bright and dark flocculi moving at moderate radial velocities, by using the lowest dispersion and widest second slit compatible with good definition and contrast.[3] But the discriminating power of high dispersion is very advantageous in many cases, and a means of utilising it without the limitations incident to the simultaneous use of only two second slits, or the delays involved in making a series of exposures like that in Fig. 8, is clearly desirable, especially in the case of rapidly changing eruptions. This is afforded by the spectrohelioscope, because of the ease of quickly shifting the position of the $H\alpha$ line on the second slit while observations are in progress. Of the various devices I have employed for this purpose, perhaps the simplest is a piece of plane parallel glass, mounted on trunnions just below the oscillating second slit. When this glass plate is tipped up or down, the line is displaced to red or violet. A scale in the eye-piece shows the exact position of the line on the slit. This is readily converted into a 'blink' apparatus for comparing the images of the flocculi corresponding to the red and violet edges of the line. An electro-magnet for tipping the plate and two adjustable stops to define its limits serve for this purpose.

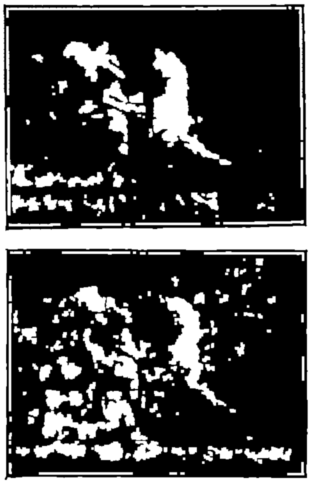

FIG. 9.—Two photographs of the hydrogen flocculi associated with an active sunspot group, made simultaneously with light from the violet (upper) and red (lower) sides of the $H\alpha$ line. The bright eruptive regions are similar in the two cases, while the lower photograph shows also the dark flocculi caused by the absorbing gas at higher levels, descending toward the photosphere.

With a device of this kind, or with a micrometer screw which permits the oscillating bar (and thus the second slit) to be displaced toward red or violet (shown near the centre of Fig. 6), it is fascinating to watch the changes in the appearance of the flocculi, and to distinguish between ascending and descending gases. In fact, we have here a special means of analysing the $H\alpha$ line and of separating the complex elements of which it is composed. Areas in the solar atmosphere which give rise, for example, to bright $H\alpha$ lines displaced toward the red frequently lie in the line of sight or in such close proximity that they cannot be distinguished in photographs of the $H\alpha$ line in the spectrum of the region. Thus in measuring the displacement of this line near spot groups or in other parts of the sun's disc we are dealing with an integrated effect, representing the superposition of the various $H\alpha$ lines given by the superposed or closely contiguous areas in question. With the spectrohelioscope many of these areas can be separately distinguished and their radial velocities determined by moving the line back and forth over the second slit and noting the displacement from its centre, towards red or violet, when a given bright or dark structure reaches its maximum of intensity. Furthermore, the width of the bright or dark $H\alpha$ line corresponding to any detail of structure can also be measured by taking the scale readings, to red and violet, at which this structure disappears. Indeed, it would not be difficult, by a simple photometric device, to determine the exact intensity curve of the line given by any of the small flocculi.

---

[3] Or (if higher dispersion is employed) the $H\alpha$ line may be caused automatically to move back and forth across the narrow second slit during the exposure.

I am referring to observations within the boundaries of the dark $H\alpha$ line and its two wings (each of which is about as wide as the dark line itself), and not to the large local displacements which are often seen in or near active spot groups. It should be added, however, that the spectrohelioscope is also well adapted for the observation of the rapidly moving gases which give rise to these large displacements. The form of the gas moving at any given velocity can be seen by setting the oscillating slit at the corresponding distance from the centre of the line.

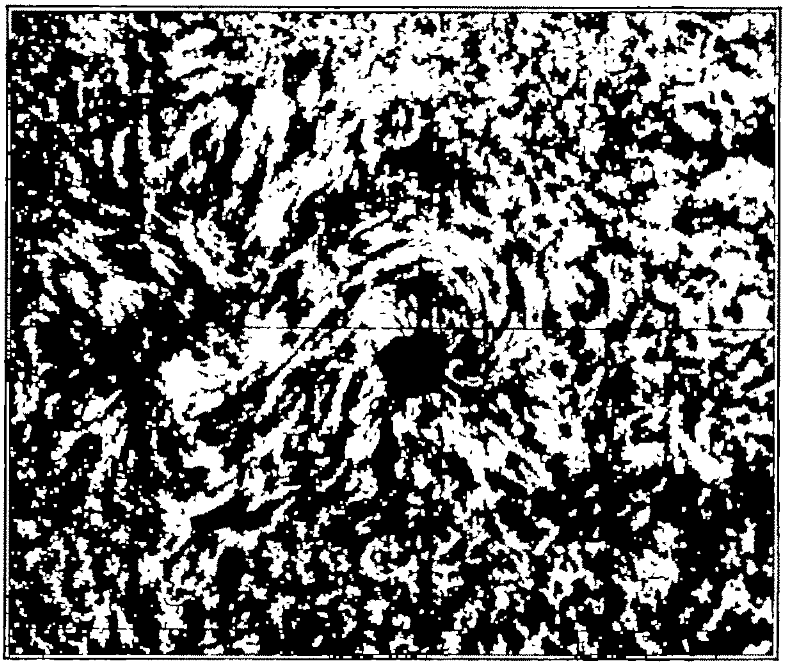

FIG 10.—Hydrogen ($H\alpha$) vortex photographed by Benioff at Mount Wilson with the 13-foot spectroheliograph. Simple vortices of this character are selected for determining the law of storms in the solar atmosphere.

PROMINENCES, FILAMENTS, VORTICES, AND ERUPTIONS.

Even for the observation of prominences projecting outside the limb, the oscillating slit has some advantages over the wide slit. This is because the former shows them in essentially monochromatic light, and thus often permits details to be seen which are confused with a wide slit because of the superposition of gaseous masses moving at different velocities in the line of sight. By setting the oscillating slit on different parts of the line, portions of the prominence moving at different velocities can be seen separately, as in the case of the flocculi just cited. Prominences in which there are marked internal differences of radial velocity sometimes do not appear at all on the disc at the slit position which shows them best outside the limb. A turn of the micrometer screw, however, suffices to reveal them in strong contrast, either as filaments or in other forms.

This suggests the use of a spectrohelioscope as a guiding device for a spectroheliograph, permitting the $H\alpha$ line to be frequently readjusted on the second slit of the latter instrument during exposures, so as to record all phenomena at the limb and on the disc in strongest contrast. The spectrohelioscope itself may also be used for photography, either in the form described here, provided with an auxiliary camera and right-angle prism for visual observations between exposures on small areas; or as a spectroheliograph with oscillating slits, capable of photographing the entire solar disc. With the former arrangement, the changes in the appearance of given areas when $H\alpha$ is moved across the second slit may be recorded, perhaps even in the form of moving pictures.

I cannot dwell, however, on the remarkable phenomena thus brought to view. Some of them are illustrated in Figs. 2 and 11, but these spectroheliograms are quite inadequate to show the delicate details,[4] and they of course fail to indicate the effect of shifting the line on the slit. Brief reference should be made, however, to observations of vortices and eruptions.

I have previously described in NATURE our researches at Mount Wilson on the law of sunspot polarity.[5] This is part of a more general investigation on the law of whirling storms in the sun, which we find to be much more complicated than the terrestrial law. The bipolar vortices which constitute typical sunspots are of opposite polarity in the northern and southern hemispheres of the sun, and these polarities are reversed at each sunspot minimum. The available evidence favours the view that this magnetic change is due to a reversal in the direction of whirl in the vortices that produce the spots and their magnetic fields. These vortices in the photosphere are accompanied by secondary vortices in the overlying atmosphere, recorded (as in Fig. 10) by the spectroheliograph. From a preliminary study[6] it appears that the direction of whirl in about 80 per cent. of the high-level vortices accompanying single spots (or the preceding spots of bipolar groups) corresponds with that of terrestrial storms, and does not reverse at sunspot minima.

---

[4] This remark refers to our spectroheliograms with 2-inch solar image. The details of the vortex structure are best shown by our spectroheliograms of the 6¾-inch solar image given by the 60-foot tower telescope on Mount Wilson (see Figs. 3 and 10). I am not yet certain whether the most delicate details on such photographs can be so well seen with the spectrohelioscope.

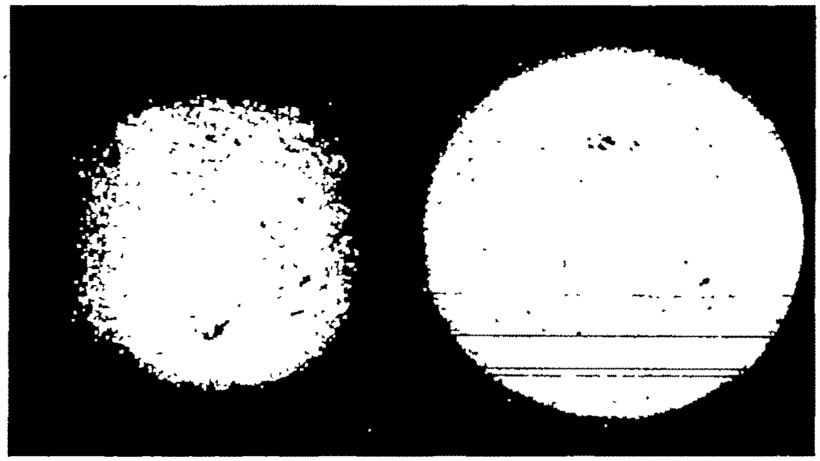

FIG. 11.—Bright eruption in great sunspot group at 22° N latitude, photographed at Mount Wilson with the 13-foot spectroheliograph, January 24, 1926, at 9h 34m Pacific standard time. The image on the right is a direct photograph of the sun, obtained simultaneously with hydrogen ($H\alpha$) image on the left. This eruption was detected independently in Pasadena with the spectrohelioscope.

The above results were derived from an examination of spectroheliograms, but I have found the spectrohelioscope a very useful means of continuing the investigation. If, as often happens, a prominence (or filament) occurs as a dark flocculus near a spot, its spiral form may at once indicate the direction of whirl in the vortex. Owing to differences in radial velocity, a slight change in the position of the $H\alpha$ line on the oscillating slit is frequently necessary to show such a vortex clearly. For detailed studies of vortex structure and changes of form, both in plan on the disc and in cross-section at or near the limb, the spectrohelioscope has also shown its efficiency.

This instrument is also of great service for the detection of such violent outbursts on the sun as I observed on January 24 (Fig. 11) and 25, 1926, preceding the great aurora and magnetic storm of January 26 and 27 already described in NATURE (February 6, p. 208). The eruption, which continued for several hours on January 25, surpassed in brilliancy all solar phenomena I have ever before seen, and exhibited rapid changes of form.[7] Because of the ease of glancing occasionally during the day at probable regions of activity, and of instantly finding the best possible position of the second slit on $H\alpha$, the spectrohelioscope should greatly assist in determining the true relationship between solar eruptions and terrestrial auroras and magnetic storms. If, as I hope, an inexpensive instrument can be built for the use of amateurs, the chances of detecting the exact moments of critical outbursts will be greatly multiplied. A small spectrohelioscope for this purpose, and improved oscillating and rotating slits to replace the oscillating bar hitherto employed with the 13-foot spectrohelioscope, are now under construction and will soon be ready for trial.

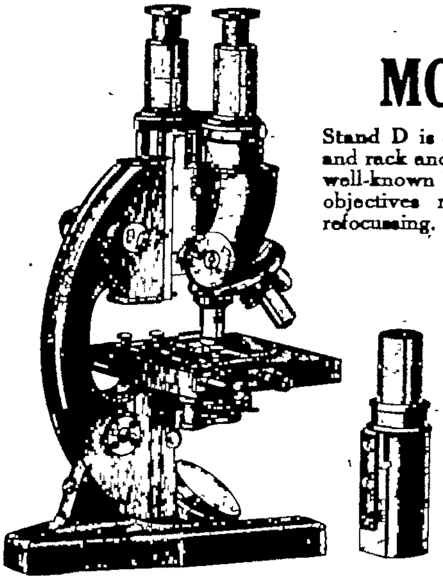
NEW MODEL MONO-BINOCULAR STAND



'Stand DSG

Stand D is of entirely novel design, and fully inclinable. The limb is shaped, and rack and pinion focussing is provided to a simplified type of substage. The well-known Meyer toothed-wheel slow motion is supplied. The nosepiece and objectives remain in position when the bodies are changed, thus obviating refocussing. The stand is supplied in three types:

- DSA with simplified mechanical stage.
- DSC with fixed square stage.
- DSG with square-pattern, built-in, mechanical stage.

A SHORT HISTORY OF CHEMISTRY

By ROSE STERN, B.Sc.
North London Collegiate School

WITH DIAGRAMS AND PORTRAITS

Cloth Boards. 160 Pages. **2s. 6d.**

SECOND LARGE EDITION

Miss Stern has planned her book to meet the need for a simple treatment of the subject. It is written from the humanistic point of view, and presents the essential outlines of the history of chemistry without the mass of facts which load the standard works.

From the "Chemical News":

"There are few good histories of chemistry, and hardly one can claim to be suitable for young readers. The attention of Science Masters and Mistresses is therefore directed to Miss Stern's interesting little volume on the subject. Indeed, none of the contents of the book can be criticised; the subject has been presented so admirably, and gives a clear idea of the gradual growth of chemical knowledge.

SCIENCE

AN INTRODUCTORY TEXT-BOOK

By E. J. HOLMYARD, M.A., M.Sc., F.I.C.
Late Scholar of Sidney Sussex College, Cambridge, Head of Science Dept. Clifton College; Examiner in Chemistry (Matriculation) to the University of London, Member of the Royal Asiatic Society.

Cloth Boards. 240 Pages. **4s.**

EXTRACT FROM AUTHOR'S PREFACE:

This little book is an attempt to present science as a whole to young students. No division of the work into the usual water-tight compartments has been made, and reference has been made throughout to phenomena of everyday life. The difficulty of teaching General Science has been, I believe, mainly due to the fact that too much was attempted. Teachers have not courageously recognised that in an elementary course on General Science many things must perforce be omitted, and the consequence has been that the average scheme degenerates into a collection of snippets from chemistry, physics and biology. I do not hope to have overcome these difficulties altogether, but I have tried to surmount them by taking the four Aristotelian elements as the framework of my scheme. A short treatment of biological subjects has followed naturally.

The greater portion of the course described has been in use for some years at Clifton College, for the most part with gratifying success.

THE BRITISH DRUG HOUSES, LTD.

Makers of Fine Chemicals

Graham Street, London, N.1

has allocated this space to

THE SOCIETY OF CHEMICAL INDUSTRY

for the announcement of the

ANNUAL GENERAL MEETING AND CONGRESS OF CHEMISTS

in London, July 19–25, 1926.

Special attention is directed to the Meeting on July 20, dealing with
"Scientific and Industrial Problems presented by the Hormones—the Natural Drugs of the Body."

Any reader of this journal, who is interested, is invited to apply for full programme of the Congress to The General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C.2.

If you have any

DEFECTIVE MICRO. OBJECTIVES

either Apochromatic or Achromatic, by

ZEISS, LEITZ, REICHERT, or OTHER MAKERS

we are prepared to examine and report on them with a view to repair.

FOR EFFICIENCY AND ECONOMY

USE PYREX

Because of its superior strength in resisting heat and rough usage, PYREX is the ideal laboratory glassware for schools, colleges and industrial institutions

PYREX minimises breakage from mechanical shock. It is highly resistant to sudden cooling, and a PYREX Rod heated to 300° C. will not break when plunged into cold water.

PYREX will withstand water, mineral acids, carbonates, alkalis, ammonia and ammonium salts to a remarkable degree.

PYREX is stocked by all reliable dealers in laboratory apparatus.

WHAT THE EXPERTS SAY

"The Leica Automatic Film Camera is a superlative piece of mechanism. It is in all respects a singularly efficient, practical instrument, capable of covering a wide category of work. The finder gives an exceedingly brilliant, sharp image of the field in all conditions of lighting."—*The Photographic Journal* (the official organ of the Royal Photographic Society), March 1926.

"A camera which is unique and efficient, both terms being scientifically accurate. The camera is a marvel of diminutiveness and portability, and eminently suited for travellers and tourists"—*The Camera*, May 1926.

"A camera of decidedly novel design and a high-class instrument of precision. The definition at full aperture is excellent, and the view finder places the subject correctly in all cases"—*The Amateur Photographer*, May 27, 1925.

"An innovation in pocket cameras, with an excellent direct-vision finder. The design and workmanship are of the highest description."—*The British Journal of Photography*, June 1925.

THE
EMERALD
Valve Wave-meter
200-600 metres
Designed by Lieut.-Col. K. E. EDGEWORTH, D.S.O., M.C., A.M.I.E.E.
(Patents applied for.)

The Instrument is being placed on the market with a view to meeting the demand for an accurate and permanent standard of wave-length at a reasonable price. Its special features are:—

1.—The wave-length is read directly on the geared dials without the use of calibration charts.
2.—The calibration is not affected by moderate changes in high or low tension voltage
3.—The valve can be replaced without affecting the calibration.
4.—The accuracy is high In the present pattern, covering 200-600 metres, the readings are correct within 1 metre.
5.—The construction is robust, the condenser bearings are of ample size to provide against wear, and the whole instrument is designed with a view to permanence and accuracy.
6.—The instrument is effectively screened, and is free from effects due to stray capacity

Price - - - £5 17s. 6d.

THE RESEARCH FOUNTAIN PEN (Patented).

Price 20s. free by post.

A hardy and most durable self-filling and safety pen which is ***entirely cleanly*** and ***entirely reliable***. In certain localities the Research Pen is known as the "doctor's pen," and it certainly supplies him with the much needed want of a pen which ***never makes a blot*** and which is so reliable that it ***requires no shaking*** to start it writing. For out-of-doors use the Research Pen offers the further advantages that it is scrupulously cleanly for the fingers and the penholder in the filling (and at all times), that it holds double the quantity of ink of other self-filling pens, and that the quantity of ink within the pen may at any time be clearly seen through its transparent bakelite walls. All of which new qualities, it may be remarked, are equally valuable in-doors as out-of-doors

But it is as a pen for the library and the office that the Research Pen excels to the utmost, and we say with all the confidence which testimonials of the most definite and grateful character can give, that the Research Pen is immeasurably superior to every form and fashion of dip pen. Former fountain pens could scarcely be said to compete seriously with the dip pen for office, etc., use. The dip pen gave the maximum of reliability, it could not flood, and it was distinctly less liable to blot. The advantage of continuous writing without re-dipping as given by former fountain pens was greatly offset by the longer periods when there was too little ink on the nib, and when in consequence a greater pressure on the paper was required and writing was rendered more difficult. Now in the dip pen, the shortness of ink on the nib could at any moment be restored by re-dipping, and the dip pen was par excellence the only pen for the artist, the draughtsman, and the fine writer. Nothing can exceed the ease of writing of a dip pen newly raised out of the inkpot; unfortunately, it only lasts for 1 or 2 words. Other fountain pens—in their periods of alternate flooding and scantiness—pass and repass this desirable position when writing is at its best. The chief merit of the Research Pen is that it maintains—unlike dip pens and unlike all other fountain pens—a full and ***uniform*** quantity of ink on the nib; it equals the dip pen at its best, and it remains indefinitely at that best. There is no flooding. It exceeds the dip pen as a pen for the artist, etc.

The Research Pen establishes a new and much higher standard in EASE and SPEED of writing; no trouble is experienced in filling and using the pen, and no statement is made regarding the pen which is not strictly true.

Writers should state if broad, medium, or fine pointed gold nib is desired, and if of hard, medium, or soft spring. Nibs may be changed until suited. Relief nibs, and nibs for manifold writing, are also supplied.

A. MUNRO, Fountain Pen Manufacturer,
248 Corporation Street, BIRMINGHAM.

"In years to come the publication of this monumental work will rank as one of the milestones in British applied science."—*Nature.*

Scientific Publications

Practical Physiological Chemistry. By S. W. COLE, M.A., University Lecturer in Medical Chemistry, Cambridge.

7th Edition, entirely revised and rewritten. Well illustrated. Demy 8vo, cloth. 16s. net. (Postage 1s.)
"This excellent practical book."—*Lancet.*

Fundamentals of Bio-Chemistry in Relation to Human Physiology. By T. R. PARSONS, B.Sc., M.A.

Crown 8vo, cloth. 10s. 6d. net. (Postage 6d.) An invaluable little book dealing with the chemical processes at work in the body. With a new chapter added on "Insulin." 2nd Edition.
"An admirable introduction."—*Medical Review.*
"This is a book to read and have. . . . In essentials the book is admirable."—*Lancet.*

The Internal Secretions of the Sex Glands. *The Problem of the Puberty Gland.* By ALEXANDER LIPSCHUTZ, M.D.

Illus. Demy 8vo. cloth. 21s. net. (Postage 9d.) An entirely new edition of a remarkable book. Strictly scientific but very readable
"The book is well planned and well written . . . the illustrations are beautiful and excellent . . . the author writes as a master."
Nature.
"The chapter on intersexuality . . . is particularly well done. . . . Profusely illustrated and containing an excellent bibliography, this book should appeal specially to the physiologist, and indeed to all students of the problems of sex and of genetics."
Edinburgh Medical Journal.

Practical Chemistry by Micro-Methods. By E. C. GREY, D.Sc.

Demy 8vo, cloth. 4s. 6d. net. (Postage 4d.) A new method, revolutionary, but simple, accurate and extremely economical.
"Strikes an entirely new note."—*Chemistry and Industry.*
"The method is simplicity itself."—*Medical World.*
"Excellent little work."—*Prescriber.*

Practical Physical and Colloid Chemistry for Students of Medicine and Biology. By L. MICHAELIS. Translated by T. R. PARSONS.

Demy 8vo, cloth. 7s. 6d. net (Postage 6d.) Illustrated by instructive practical exercises.
"An excellent book, ably translated."—*B. M. J.*

Notes on Geological Map-reading. By A. HARKER, LL.D., F.R.S., etc.

Demy 8vo, sewed. 3s. 6d. net. (Postage 3d.) A new edition revised. Illustrated.

The Arab Civilization. By JOSEPH HELL. Translated by S. KHUDA BUKHSH.

Demy 8vo, cloth. 8s 6d. net. (Postage 6d.) In the translator's opinion the most up-to-date and able account of the Arab civilization.

APPARATUS
for the measurement of
RADIO-ACTIVITY

This apparatus is designed for obtaining comparative measurements of radio-activity for different substances. The substance is placed on the lower of two insulated plates between which a difference of potential is maintained, and the radio-activity is measured by determining, by means of an electrometer or electroscope, the leakage of electricity between the plates due to ionisation of the gas.

UNIVERSITY OF ST. ANDREWS.

LECTURESHIP IN PHYSICAL CHEMISTRY IN UNIVERSITY COLLEGE, DUNDEE.

The University Court of the University of St. Andrews invites applications for the vacant LECTURESHIP IN PHYSICAL CHEMISTRY in University College, Dundee. Salary £500. The Lecturer to be appointed will enter upon his duties as at October 1, 1926.

Further particulars will be furnished by the undersigned. Three printed or typewritten copies of the letter of application and relative testimonials should be lodged with the undersigned on or before August 16. Candidates are requested to submit at least three testimonials, or, alternatively, to furnish the names of three referees.

The University, St. Andrews
July 6, 1926

ANDREW BENNETT,
Secretary and Registrar.

KENT EDUCATION COMMITTEE.

COUNTY SCHOOL FOR GIRLS, BECKENHAM.

A CHIEF SCIENCE MISTRESS will be required in September to organise the Science work of the School and to teach to the Higher Certificate standard. Preference will be given to candidates holding an Honours Degree (First or Second Class) in Botany with subsidiary Chemistry. Owing to the lateness of the advertisement, a temporary appointment of a less well-qualified candidate may be made

Applications for a temporary post until Christmas, and for a permanent post in September or January, should be made at once to the Head Mistress. Letters should be marked "Science Post" Testimonials will be returned only if a stamped envelope is enclosed.

E. SALTER DAVIES, Director of Education.

UNIVERSITY OF DURHAM

(ARMSTRONG COLLEGE),

NEWCASTLE-UPON-TYNE.

LECTURESHIP IN ZOOLOGY.

The Council of Armstrong College invites applications for a LECTURESHIP as above Salary £250 or £300 per annum, according to experience and qualifications Duties to commence on October 1, 1926. Special qualifications in Marine Zoology desirable Ten copies of applications and of not more than three testimonials should be received not later than Saturday, August 28, 1926, by the undersigned, from whom further particulars may be obtained J Y T. Greig, Registrar, Armstrong College.

GOVERNMENT LABORATORY.

TEMPORARY ASSISTANT CHEMISTS wanted, age 20-25. Required to have degree of B.Sc. with not less than Second Class Honours or equivalent; weight will be given to experience in investigative work. Salaries men £160-£10-£220, women £140-£10-£180, plus usual Civil Service Bonus; at present £160 is equivalent to £258. 8s. and £140 to £231. Preference will be given to ex-Service men, and candidates will be allowed to deduct from their actual ages any time spent with the Forces between August 1914 and November 1918 Forms of application may be obtained from the Government Chemist, Clement's Inn Passage, London, W C.2, to whom they must be returned not later than July 31.

MIDLAND AGRICULTURAL AND DAIRY COLLEGE.

APPOINTMENT OF ADVISORY AGRICULTURAL ECONOMIST.

The Governors of the above College invite applications for the post of ADVISORY AGRICULTURAL ECONOMIST. Salary £400-£450 per annum, according to qualifications and experience, less 5 per cent. Superannuation contribution, the College contributing 10 per cent. thereto. Further particulars from Thos Milburn, Principal, Sutton Bonington, Loughborough

Applications are invited for the position of

ASSISTANT at the Commonwealth of Australia Observatory at Mount Stromlo Salary £804 to £900 per annum, less 10 per cent deduction for rent. Applications in triplicate, together with testimonials, should be addressed to the High Commissioner for Australia, Australia House, Strand, London, W C 2, and be received not later than July 22, 1926. Further particulars obtainable from Room 306, Australia House

UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH.

Applications are invited for the post of ASSISTANT LECTURER IN PURE MATHEMATICS. Salary £250 to £300 per annum, according to qualifications and experience. For further particulars apply to the Secretary, to whom applications should be sent before July 29.

Laboratory Assistant, 15 years' experience,

Secondary and University, requires post, Chemistry, Physics or Experimental Instrument work. Box 138, c/o Nature Office.

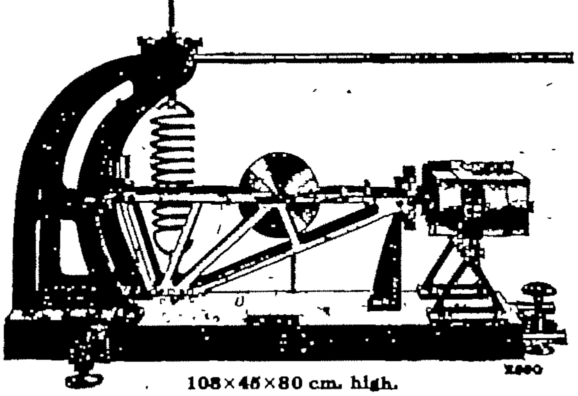
GALITZIN SEISMOGRAPHS

AS SUPPLIED TO:
Seismological Observatory,
West Washington, U.S.A.;
Naval Observatory,
Kobe, Japan;
R. Osservatorio Geofisico,
Pavia, Italy.
Instituto Geografico,
Madrid, Spain.



108×45×80 cm. high.

The illustration shows a seismograph for indicating the vertical component of disturbance.

Further particulars, with illustrations and detailed drawings of the horizontal component seismograph, will be forwarded on request.

These instruments are similar in design to those made by the late Prince Boris Galitzin for the recording of small seismic disturbances. The instruments record the two horizontal components and also the vertical component of disturbance. Efficient electro-magnetic damping is provided, which does not impair the sensitiveness of the instruments.

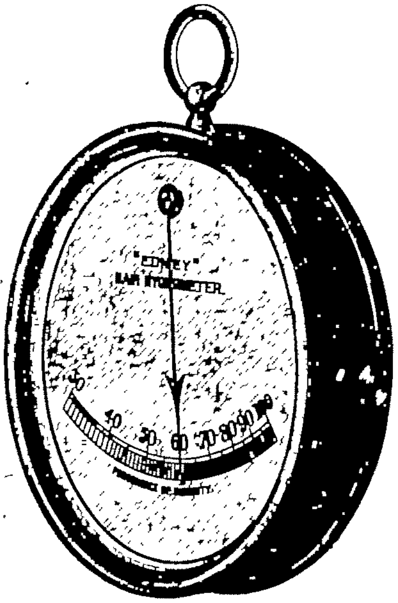
"Edney" Hair Hygrometers

showing directly the PERCENTAGE of MOISTURE in the room or other position where placed



No. 1

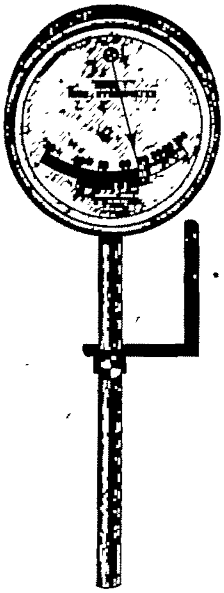
THE instruments are strongly made, and mounted in stout polished and lacquered brass cases, with 5-inch engraved and silvered metal dials which give a very open range, allowing the variations in humidity to be easily observed.

The action is by the contraction or expansion of a strand of 50 specially treated human hairs, which alters in length according to the percentage of moisture in the atmosphere.

This movement is conveyed by simple mechanism to a pulley on which the indicating hand is fixed.

Each instrument is tested against Standard Wet and Dry Bulb thermometers, and is guaranteed to give accurate readings.

A small adjusting screw is provided so that at any time the hand can (if required) be set to a standard.



No. 2

CAMBRIDGE ACCELEROMETER

for measuring accelerations of
MOTOR VEHICLES,
RAILWAY COACHES,
AEROPLANES,
LIFTS, ETC.

Full particulars are given in our new List No. 149-N.

The Cambridge Accelerometer provides a convenient means of studying the springing of vehicles and the effect produced on them due to the surfaces upon which they travel. It can be used for measuring either vertical or horizontal accelerations. The records, which are clear and permanent, are obtained by means of a stylus acting upon a moving celluloid strip. The illustration is an enlargement (15x) of an actual record taken on an 8 H.P. Rover car travelling at 28 m.p.h.

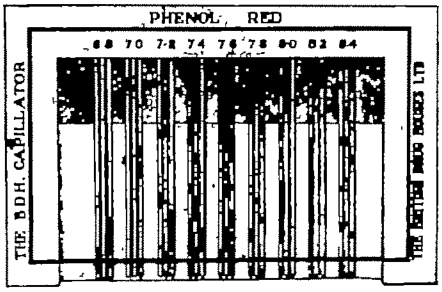
Special Lists on request

B.D.H. CAPILLATOR

THE B.D.H. "Capillator" provides an improved method for the colorimetric determination of Hydrogen Ion Concentration.

The "Capillator" consists of a series of capillary tubes filled with buffer solutions containing an indicator. These tubes are mounted in threes on a white card, and form a series of coloured strips, each strip being marked with its exact PH value. Each card illustrates the complete colour change of the indicator.



A determination of PH is carried out by mixing equal quantities of liquid and indicator, and comparing the colour produced with that of the standard tubes of the "Capillator." By means of the "Capillator" determinations of PH are carried out expeditiously and accurately, and as little as one drop of the liquid will suffice for a test.

Prices and further particulars will be supplied on application.

"G"	Galvanometers, moving coil, pointer and reflecting.
"OG"	Galvanometers, "Onwood" pattern.
"GA"	Galvanometer Accessories, including Lamps, Scales, Universal Shunts, etc.
"K.S"	Keys and Switches.
"IR"	Gambrell's "Independent" Plug Contact Resistance Boxes and Wheatstone Bridges.
"HR"	Megohms and High Resistances.
"SR"	Switch pattern Resistance Boxes and Wheatstone Bridges, all grades, including Direct Reading.
"P.K"	Potentiometers, Kelvin Low Resistance Bridges, Kelvin Double Ratio Box, Volt Ratio Boxes, Standard Cells, Low Resistance Shunts.
"RR"	Rheostats and Single Resistances.
"C"	Condensers, Standard and Secondary.
"V.A"	Voltmeters, Ammeters, Milliameters.
"T.A"	Apparatus for Electro-Titration.

Journal of Scientific Instruments

(Published on the 15th day of each month.)

PRODUCED BY THE INSTITUTE OF PHYSICS, WITH THE CO-OPERATION OF THE NATIONAL PHYSICAL LABORATORY.

PRICE: SINGLE COPIES, 2s. 6d. ANNUAL SUBSCRIPTION, 30s., including postage. Send subscriptions to the CAMBRIDGE UNIVERSITY PRESS, Fetter Lane, London, E.C 4

CONTENTS OF JULY ISSUE.—VOL III, No. 10

SUPPLEMENTARY NOTE ON THE PASCHEN GALVANOMETER. By H A. DAYNES.

A SIMPLIFIED MOVING MAGNET GALVANOMETER WITH A HIGH FIGURE OF MERIT. By A C. DOWNING

A "MUMETAL" MAGNETIC SHIELD FOR A SENSITIVE GALVANOMETER. By PROF. A V. HILL

NOTE ON MICROSCOPE TUBE LENGTH. By T F CONNOLLY

A VACUUM-TUBE MULTIMETER FOR RADIO-FREQUENCY MEASUREMENTS. By M. V. COLBY

A NOTE ON THE MEASUREMENT OF CURRENTS BY THE ELECTRONIC EMISSION FROM HEATED WIRES. By JAMES TAYLOR

NEW INSTRUMENTS: VACUUM THERMO ELEMENT. Designed by DR MOLL.

A SELF-STARTING PHONIC MOTOR By D.C. GALL.

LABORATORY AND WORKSHOP NOTES.

LUBRICATION OF FINE MECHANISMS WITH MINERAL OIL.

NOTE ON THE CONSTRUCTION OF SMALL THERMO-COUPLES By J. DICKSON HANNAH.

POSSIBILITIES OF THE SUBDIVIDED MEGOHM. By E. H. W. BANNER

THE REVIVAL OF THE MOVING MAGNET GALVANOMETER.

NOTE ON THE MANUFACTURE OF QUARTZ JAWS FOR SPECTROMETER SLITS By G. H. CARRUTHERS.

CORRESPONDENCE.

THE NATIONAL PHYSICAL LABORATORY TEDDINGTON.

TABULAR INFORMATION ON SCIENTIFIC INSTRUMENTS: X. VIBRATION GALVANOMETERS

This journal is devoted to the needs of workers in every branch of science and manufacture involving the necessity for accurate measurements. Its scope includes Physics and Chemistry, Optics and Surveying, Meteorology, Electrical and Mechanical Engineering, Physiology and Medicine.

With the October number a new volume began. Vols. I. and II. can be obtained complete, bound in cloth, for 35s. each

That Book you want!

Foyles can supply any Scientific Book that is in print and most of those that are out of print. They have a Special Department for this class of literature under a Manager who has experience and knowledge of the Natural Sciences. Call and consult him, or write and you will get an intelligent reply. Books sent on approval. Over a million volumes Second-hand and New on every conceivable subject in stock. Twenty-one Departmental Catalogues issued, any of which will be sent gratis and post free on mentioning interests.

That Book you do not want!

Foyles will buy it.—A single volume to a library.

Expert valuers sent any distance.

FOYLES, 121 Charing Cross Road, London.

¶ W. HEFFER & SONS, Ltd., 4 PETTY CURY, CAMBRIDGE, will be glad to receive offers of Complete Libraries, Sets of Journals, and Smaller Collections of Books, for which they are prepared to offer full current value and pay cash.

¶ They have a very highly organised department for the supply to Librarians, Institutions, and others, of Scientific Books and Journals, both English and Foreign (new and second-hand).

¶ CATALOGUE 269. Scientific Books and Publications of learned Societies.

Licensed Valuers for Probate.

Telegrams and Cables: HEFFER, CAMBRIDGE Telephone. [illegible]

THE

DINOFLAGELLATES OF NORTHERN SEAS

By MARIE V. LEBOUR, D.Sc., F.Z.S.

Naturalist at the Laboratory of the Marine Biological Association of the United Kingdom, Plymouth.

Cloth, 8vo, 250 pp., 53 text-figures, 35 plates.

Price **12s. 6d.** net. Post free 13s.

Published by the Marine Biological Association of the United Kingdom, October 1925.

Copies may be obtained from THE DIRECTOR, Marine Biological Laboratory, Citadel Hill, Plymouth; MESSRS. DULAU & Co., LTD, 34-36 Margaret St., Cavendish Square, London, W 1; or any Bookseller

SOTHERAN'S CATALOGUE OF SCIENCE AND TECHNOLOGY.

Already published. Part I: Sets of Scientific Periodicals, General and Collected Works (pp. 80). Part II: Mathematics (pp. 128). Part III: Astronomy, Geodesy, Chronology, Horology, and Dialling (pp. 112). Part IV: Physics, Letters A-R (pp. 112). Part V: Physics, Letters S-Z, and Supplement pp. 56. Part VI: Geology, Meteorology and Physical Geography, Mineralogy and Crystallography; Microscopy (pp. 144). Just published: Part VII: Chemistry and Chemical Technology (pp. 208). In preparation: Part VIII: Mining and Metallurgy.

"This special catalogue of Messrs. Sotheran needs no recommendation, being well known for its valuable bibliographic notes, and the number of choice and rare books offered for sale."
NATURE.

Messrs Sotheran are always ready to buy libraries or smaller collections of books on exact science, as well as sets of scientific periodicals. They invite correspondence in connection with books rare and difficult to get.

Recent Scientific and Technical Books.

Volumes marked with an asterisk have been received at "NATURE" *Office.*

Mathematics: Mechanics: Physics

Andrews, E. S. Mechanisms: a Text Book for the Use of Non-Technical Students. Large Cr. 8vo. Pp. viii + 194. (London: University Tutorial Press, Ltd., 1926.) 3*s.* 6*d.*

Ballard, P. B. Fundamental Arithmetic. Cr. 8vo. Pupil's Book 1. Pp. 65. Paper, 10*d.*; linen, 1*s.* Teacher's Book 1, with Notes and Answers. Pp. 48. 2*s.* (London: University of London Press, Ltd., 1926.)

Bocher, Maxime. An Introduction to the Study of Integral Equations. 8vo. (Cambridge: At the University Press, 1926.) 4*s* 6*d* net.

Carleman, T. Les fonctions quasi-analytiques: leçons professées au College de France. (Collection de Monographies sur la Théorie des Fonctions.) 8vo. Pp. 116 (Paris: Gauthier-Villars et Cie, 1926.) 36 francs.

Curtiss, David Raymond. Analytic Functions of a Complex Variable (The Carus Mathematical Monographs: published for the Mathematical Association of America.) Cr. 8vo Pp. ix + 173 (Chicago and London: The Open Court Publishing Co, 1926.) 10*s.* net.*

Donder, Th. de. Théorie des champs gravifiques (Mémorial des sciences mathématiques, Fascicule 14.) Roy 8vo. Pp. iii + 60. (Paris: Gauthier-Villars et Cie, 1926.) 12 francs.*

Grieve, A. Barrie. Analytical Geometry of Conic Sections and Elementary Solid Figures. Part 1. Cr. 8vo. Pp 180 (London: G. Bell and Sons, Ltd., 1926.) 5*s.*

Havelock, T. H. Theory of Ship Waves and Wave Resistance 8vo. (London: E. and F. N. Spon, Ltd., 1926.) 3*s* 6*d* net

Laemel, Rudolph. Introduction to the Theory of Relativity. (Cosmos Library.) Cr. 8vo Pp. 66. (London: Simpkin, Marshall and Co., Ltd, 1926.) 1*s.* net

Lay, Ed. J. S. The Pupils' Class-Book of Arithmetic. Book 7: For the Higher Classes. Cr. 8vo. Pp. 256. (London: Macmillan and Co., Ltd, 1926.) 2*s* 3*d.*

Leconte, Th., et Deltheil, R. Éléments de calcul différentiel et de calcul intégral. (Collection Armand Colin.) 2 vols Cr. 8vo. Tome 1. Pp. 220 Tome 2. Pp 220 (Paris: Armand Colin, 1926.) 24 francs.

Medical Research Council: Industrial Fatigue Research Board. Report No 37: Fan Ventilation in a Humid Weaving Shed; an Experiment made for the Departmental Committee on Humidity in Cotton Weaving. By S. Wyatt, assisted by J. A. Fraser and F. G. L. Stock Roy. 8vo. Pp. v + 31. (London: H M Stationery Office, 1926.) 1*s* 9*d.* net.*

Metz, André. Les nouvelles théories scientifiques et leurs adversaires: la relativité. Quinzième édition. Cr. 8vo. Pp 270 (Paris: Étienne Chiron, 1926.) 9 francs.

Pincock, J. C. Geometry for Secondary Schools Cr. 8vo. Pp viii + 309. (London, Calcutta and Sydney: George G Harrap and Co, Ltd., 1926.) 3*s.* 6*d.*

Pöschl, Theodor, Herausgegeben von. Berechnung von Behaltern nach neueren analytischen und Graphischen Methoden. Zweite Auflage (Berlin: Julius Springer, 1926.) 15 60 marks.

Potter, F. F., and **Rice, F. C.** Common-sense Arithmetic: a Junior Textbook. Cr. 8vo Pp. xvi + 320 (London: Sir Isaac Pitman and Sons, Ltd, 1926.) With Answers, 4*s.* 6*d.*; without Answers, 3*s.* 6*d.*

Reynolds, C. L. Electricity and Magnetism. (Bell's Natural Science Series.) Part 1. Cr. 8vo. Pp. 210 (London G. Bell and Sons, Ltd., 1926.) 3*s.*

Rufini, E. Il "Metodo" di Archimede e le origini dell' analisi infinitesimale nell' antichità. (Collezione Per la storia e la filosofia delle Matematiche, 4.) Cr. 8vo. Pp. viii + 294. (Roma: Alberto Stock, 1926.) 22.50 lire.

Sachs, G., und **Fiek, G.** Der Zugversuch. (Leipzig: Akademische Verlagsgesellschaft m b H., 1926.) 12 gold marks.

Sankey, E., and **Royds, Albert.** Elementary Mathematics: specially prepared for Central Schools, Senior Elementary Schools and Upper Standards (VI, VII, VIII). Part 2: For pupils of 12-14 years. Cr. 8vo Pp. viii + 120 (London: G. Bell and Sons, Ltd, 1926.) 1*s.* 6*d.*

Siddons, A. W., and **Hughes, R. T.** A Junior Geometry: based on the various Geometry Books by Godfrey and Siddons. Cr. 8vo. Pp. x + 234. (Cambridge: At the University Press, 1926.) 4*s*

Weiss, Pierre, et Foex, Gabriel. Le magnétisme. (Collection Armand Colin: Section de physique, No. 71.) Fcap. 8vo. Pp. viii + 215. (Paris: Armand Colin, 1926.) 8.40 francs.*

NEGRETTI & ZAMBRA

38 HOLBORN VIADUCT, LONDON, E.C.1

THE RESEARCH FOUNTAIN PEN (Patented).

Price 20s. free by post.

A hardy and most durable self-filling and safety pen which is ***entirely cleanly*** and ***entirely reliable.***

Warranted not to blot or flood. ***Warranted*** to start to write without shaking the pen. No other fountain pen can give such warranties, and several other warranties even more valuable than these are given regarding the writing qualities of the pen. In particular the greater EASE and SPEED of writing is a most valuable asset to all writers.

It is necessary to understand that the Research Pen contains ***two*** new physical properties which are not present in the dip pen and are not present in ***any*** other fountain pen. In the first place, the pen automatically declines to blot or flood; it ***therefore*** also automatically declines to leak or spill ink in the pocket. Used like the ordinary fountain pen and always ready to write, yet the Research Pen may safely be carried ***point downwards*** in the pocket, although it is NOT sealed up. The absence of leaking—although extremely useful and important—is comparatively a small matter when regard is had to the far-reaching results due to the absence of blotting and flooding. No writing pen of this new character had formerly existed, and it is necessary to use a Research Pen before writers can form any adequate idea of the greater value of such a pen.

The second new physical property harnessed into the Research Pen is that it maintains a ***uniform*** and unvarying quantity of ink upon the gold nib. It is like a cistern, always four-fifths full, and which can neither overflow nor lessen. How unlike the dip pen on which the ink was ever running down, and how unlike all other fountain pens on which the ink alternately went up and down! The great fault of dip pens was that for the greater part of the time there was too little ink on the nib, and which made it necessary to press the nib hard on the paper. The same fault attached to all former fountain pens, but varied at times with too much ink!

The greater ease and speed of writing of the Research Pen is certainly due to the ink on the nib never descending below its best level.

A professor writes: "The Astronomer Royal recommends me to get one of your Research Pens."

On the vital points of complete absence of blotting and the complete continuity and ability of the Research Pen to write, it may be pointed out that the pen is now used in various observatories all over the world on their chronographs, and that various Government Astronomers have reported their great satisfaction with the pen's behaviour in overcoming difficulties formerly insurmountable Testimony to the same effect may be seen on page 249 of the "Journal of Scientific Instruments" for May 1924.

FACULTY OF ENGINEERING.

Complete courses of study, extending over either three or four years, are arranged in Civil, Mechanical and Electrical Engineering for the Engineering Degrees of the University of London and for the Diploma and Certificate of the College.

The four years' course provides, in addition to the academic training, opportunity for practical training in works.

Heads of Departments.

MECHANICAL ENGINEERING·
  Professor · G. Cook, D.Sc , M I Mech.E., A M.Inst C.E.
  Senior Lecturer: C. A Gentve, B Sc., A.M.I.Mech E.
CIVIL ENGINEERING.
  Professor: A. H. Jameson, M.Sc , M.Inst C E. (Dean).
  Senior Lecturer. C H Lobban, D Sc., A M.Inst.C E.
ELECTRICAL ENGINEERING·
  Professor: E. Wilson, M.Inst C E., M.I.E E.
  Lecturer: F. S Robertson, M I E.E.
MATHEMATICS.
  Professors: S. A. F. White, M.A., and A. E Jolliffe, M.A.

Considerable extensions have been made in the Engineering Department. These include a large additional drawing office, lecture room and laboratory for Hydraulics and Strength of Materials in the Civil and Mechanical Departments, and research rooms, including Wireless Telegraphy, in the Electrical Engineering Department. Large additions have been made to the equipment of the Laboratories in the three Departments for purposes of teaching and research.

There is a College Hostel and a large Athletic Ground.

For full information apply to the Secretary, King's College, Strand, W C.2

BATTERSEA POLYTECHNIC,
LONDON, S.W.11.

Principal—Robert H. Pickard, D.Sc., F.R.S.

Day Technical College in preparation for Polytechnic Diplomas in Mechanical, Civil and Constructional, and Electrical Engineering, Chemistry, Mathematics and Physics, and for B.Sc. and B.Sc.(Eng.) Pass and Honours Degrees of the University of London.

Training College of Domestic Science in preparation for Teachers' Diplomas in Cookery, Laundrywork, Housewifery, Science Applied to Housecraft, Needlework, Dressmaking, Ladies' Tailoring, and Millinery

Department of Hygiene and Public Health for the training of Health Visitors, Sanitary Inspectors, Infant Welfare Workers, Teachers of Hygiene, Nurses, Sister Tutors, etc.

School of Art and Crafts for training in Drawing and Design, Fashion Plate Drawing, Applied Art, etc

Hostels for Women Students.

Evening Courses in preparation for University of London Degrees in Science, Engineering, and Music, and Non-degree Courses in Mechanical and Electrical Engineering, Mathematics, Physics, Chemistry, Art and Crafts, Civil Service subjects, Domestic Science, Music, and Physical Training.

Large Athletic Ground at Merton Abbey, and numerous Athletic Clubs

Next session begins on September 21.

Full particulars of all classes on application to the Principal. Telephone BATTERSEA 0673

Manchester Municipal

COLLEGE OF TECHNOLOGY.

Principal:
B. MOUAT JONES, D.S.O., M A.(Oxon)

UNIVERSITY OF MANCHESTER.
(Faculty of Technology.)

DEGREE COURSES IN TECHNOLOGY.

The Prospectus gives particulars of the courses leading to the Manchester University degrees (B Sc Tech, M.Sc Tech., and Ph.D.) in the Faculty of Technology, in the following Departments·

MECHANICAL ENGINEERING (Prof. Dempster Smith, M B.E., M.Sc.Tech)
ELECTRICAL ENGINEERING (Prof. Miles Walker, M.A., D.Sc).
MUNICIPAL AND SANITARY ENGINEERING (G. S. Coleman, D.Sc.).
CHEMICAL TECHNOLOGY, including General Chemical Technology, Chemistry of Textiles (Bleaching, Dyeing, Printing, and Finishing), Paper Manufacture, Metallurgy and Assaying, Chemical Technology of Brewing, Electro-Chemistry, Photography, Colouring Matters, Foodstuffs, and Fuels (Prof. F. L. Pyman, D.Sc., F.R S.).
TEXTILE TECHNOLOGY (Prof. W. E. Morton, M.Sc.Tech.).

The session 1926–27 will begin on Thursday, October 7.

Prospectus will be forwarded free on application to the Registrar, College of Technology, Manchester.

EVENING INSTRUCTION in Bacteriology, Microscopy, and practical clinical and analytical Chemistry, in West End laboratory. Write "Z.S.Z," c/o Deacons, Fenchurch Avenue, E C.3.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH.

JUNIOR ASSISTANTS are wanted at the National Physical Laboratory.

Candidates should have a good Honours Degree, and preferably some research or technical experience in one of the following subjects. Physics, Engineering, Electrical Engineering.

Scale of salary £175-£15-£235 per annum plus Civil Service Bonus: initial pay approximately £267 Superannuation provision will be made under the Federated Superannuation System for Universities.

Preference will be given, other things being equal, to ex-Service men

Application must be made on a form to be obtained from the Laboratory, and must be received by the Director, National Physical Laboratory, Teddington, Middlesex, not later than September 4

UNIVERSITY OF ABERDEEN.
LECTURESHIP IN PLANT PHYSIOLOGY.

Applications are invited for the post of LECTURER IN PLANT PHYSIOLOGY in the Department of Botany. The salary proposed is from £400 to £450, according to qualifications

Applications, together with full statement of qualifications, age, and 16 copies of not more than three testimonials, to be lodged before September 15, 1926, with the Secretary to the University.

The University,
Aberdeen

H. J. BUTCHART,
Secretary.

UNIVERSITY COLLEGE, NOTTINGHAM.
DEPARTMENT OF MATHEMATICS.

The Council invites applications for the position of LECTURER IN MATHEMATICS, candidates to have an Honours Degree Further particulars and form of application, which must be returned not later than Tuesday, September 14, may be obtained from J. E. Shimeld, Registrar

---

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON).

The Governors invite applications for a PART-TIME LECTURESHIP in the Department of Mathematics. Salary £300 per annum. Further particulars and forms of application, which must be returned not later than the first post on Friday, September 17, 1926, may be obtained from the Secretary, Birkbeck College, Breams Buildings, Fetter Lane, E.C.4

Standard Exhibition Naturkundliches Heimatmuseum Leipzig, Lortzingst. 3. Evolution of paleolithic flint implements from many countries. For sale. Apply to Dr. O. Hauser, Weimar, Elisabethstr 11

WANTED.—Microscope, $\frac{1}{12}$" oil immersion object glass. Also general apparatus for Lab. Send details to The Fiona Company, Ipswich.

KING'S PATENT AGENCY LTD., 146a Queen Victoria Street, E.C.4. Advice handbook free. 40 years' refs.

B.D.H. CHEMICALS
FOR RESEARCH AND ANALYSIS

BRITISH MANUFACTURE

Over 3500 Substances for use in Research and Analysis are kept in stock, and we are continually adding to the list of our manufactures. The reliable quality of the B.D.H. Organic Chemicals and Analytical Reagents has led to their adoption by those who place the highest value on scientific accuracy.

A copy of our latest Catalogue will be supplied on application.

"Coolidge"

The tube which gives greatest certainty in X-ray practice

Wherever consistently perfect technique is being achieved in X-ray practice, wherever knowledge is taking the place of guess-work, wherever there is a satisfying certainty of procedure, there you will find the "Coolidge" tube.

The "Coolidge" tube makes success a matter of facts and figures. It gives the operator complete control over his results. It yields a measured quantity of rays of measured intensity.

Moreover, it functions steadily and consistently for hours on end, unfailingly duplicating results whenever a given set of conditions is repeated.

In physical and industrial X-ray work, where accuracy is of the utmost importance, the Coolidge tube is indispensable for the greatest measure of success.

Send for full particulars.
All types in stock.

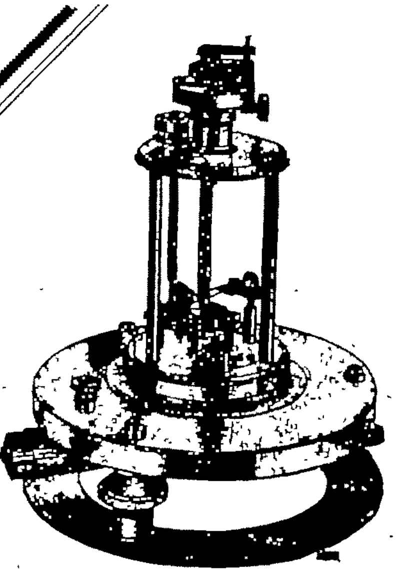
COMPTON ELECTROMETER



18 × 18 × 22 cm

This highly sensitive electrometer is based upon the design of Professors A. H. and K. T. Compton. It is of the quadrant form, and is suitable for the quick and accurate measurement of small electric charges and small potential differences. The minimum sensitivity is approx. 3000 mm. per volt per metre when the potential of the needle relative to the quadrants is 45 volts. This can be easily increased to 10,000 mm. per volt, while with careful adjustment considerably higher sensitivities can be obtained. The capacity is about 10 cm.

Further particulars sent on request.

THE UNIVERSITY OF LIVERPOOL.

DEPARTMENT OF INDUSTRIAL CHEMISTRY.

(Oils, Fats and Waxes.)

Campbell Brown Professor—T. P. HILDITCH, D.Sc.

This newly-established Department provides facilities for post-graduation students to undertake, and to receive training in, research in the field of oils, fats and waxes and subjects connected therewith.

The NEXT SESSION COMMENCES on OCTOBER 7, 1926, and Prospectuses and details as to fees may be obtained on application to the REGISTRAR, The University of Liverpool.

EDWARD CAREY, Registrar.

UNIVERSITY OF MANCHESTER.

PHYSICS DEPARTMENT.

Full particulars of the Lectures and Laboratory Courses in Physics, preparing for both the Ordinary and the Honours Degrees, will be forwarded on application to the REGISTRAR.

APPOINTMENTS BOARD OF THE IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

EMPLOYERS requiring men who have received training in Science and Technology, and who are Diplomates or Associates of the College, are asked to make use of the services of the Board. Applications should be addressed to the SECRETARY No fees are charged.

The Imperial College includes the Royal College of Science, the Royal School of Mines, and the City and Guilds (Engineering) College. Members and Associates are trained in the following: viz: Aeronautics, Applied Optics and Optical Engineering, Biology, Chemical Technology, Chemistry (all branches), Engineering (all branches, including Metallurgy, Mining, Mining Geology, and Oil Technology), Geology, Mathematics and Mechanics, and Physics.

MINISTRY OF AGRICULTURE AND FISHERIES.

Applications are invited for an appointment as ASSISTANT (Museums) at the Royal Botanic Gardens, Kew. Salary: Male Assistant £250 per annum, rising to a maximum of £600 per annum; Female Assistant £200 per annum, rising to a maximum of £450 per annum, plus Civil Service Bonus in each case. The bonus as from September 1, 1926, on £250 is £111 : 3s. per annum, and on £200, £99 per annum.

Candidates should be Honours graduates of British Universities and have had, since graduating, at least two years' experience especially of work in Economic Botany or of research work in one or more of the following botanical subjects.—Morphology, Ecology, Genetics, Systematic Botany. Candidates must also produce evidence of ability to translate from French and German

Candidates must be between the ages of 25 and 32 on October 4, 1926, except that they may deduct from their actual age any time during which they served in His Majesty's Forces during the late war. Preference will be given to ex-Service applicants.

No application will be considered unless it has been received by the Ministry of Agriculture and Fisheries on the prescribed form on or before October 4, 1926. Forms of application and copies of the Regulations can be obtained from the SECRETARY, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1.

A EUROPEAN SCIENCE MASTER is required for the Agricultural School at Moor Plantation, Ibadan, Nigeria. Candidates should be of good health, between 25 and 35 years of age, and should possess the Teaching Certificate of the Board of Education or the Scottish Education Department. They should be able to teach Mathematics, Chemistry, Physics and Botany to about Junior Local standard. Ability to teach elementary Surveying would be an additional qualification. Further information and forms of application are obtainable from the SECRETARY, C.A. (N.), Board of Education, Whitehall, London, S.W.1. Scottish candidates should apply to the SECRETARY, Scottish Education Department, S E.D. (N), Whitehall, London, S.W.1. List of applications closes September 27.

UNIVERSITY COLLEGE, NOTTINGHAM.

DEPARTMENT OF MATHEMATICS.

The Council invites applications for the position of LECTURER IN MATHEMATICS; candidates to have an Honours Degree. Further particulars and form of application, which must be returned not later than Tuesday, September 14, may be obtained from J. E. SHIMELD, Registrar.

UNION OF SOUTH AFRICA.

WITWATERSRAND TECHNICAL INSTITUTE.

Applications are invited for the vacancy for the HEAD OF THE DEPARTMENT OF CHEMISTRY.

SALARY.—Salary £450-£25-£650, plus Local Allowance, which, in the case of married officers, brings the total emoluments from £516 to £726 The initial salary will be fixed according to the existing salary, qualifications and experience of the successful applicant.

ENGAGEMENT.—The appointment will be made subject to the conditions of service laid down in the Union Higher Education Act, 1923, which may be inspected in this office.

QUALIFICATIONS.—Applicants must be qualified chemists, and the possession of qualifications of the Pharmaceutical Society of Great Britain and knowledge of Metallurgy would be a recommendation. The possession of degrees or equivalent professional qualifications and/or teaching and practical experience will be considered in making the appointment

DUTIES.—The post is a full-time one and includes both day and evening work, and the successful applicant will be required to take charge of the School of Pharmacy in addition to undertaking lectures in various branches of Chemistry.

Applications and copies of testimonials containing information as to the particulars of training, experience and present salary should be lodged with the SECRETARY, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C.2, from whom the prescribed forms of application may be obtained, not later than September 30.

UNIVERSITY OF DURHAM

(ARMSTRONG COLLEGE),

NEWCASTLE-UPON-TYNE.

ADVISER IN AGRICULTURAL CHEMISTRY.

The Council of Armstrong College invites applications for the above post, under Grade III. of the advisory scheme of the Ministry of Agriculture and Fisheries. Salary £300 per annum plus Bonus. Appointment to date from January 1, 1927.

Ten copies of applications and of not more than three testimonials should be lodged, not later than October 1, 1926, with the undersigned, from whom further particulars may be obtained.

J. Y. T. GREIG, Registrar,
Armstrong College.

BIRKBECK COLLEGE

(UNIVERSITY OF LONDON).

The Governors invite applications for a PART-TIME LECTURESHIP in the Department of Mathematics. Salary £300 per annum. Further particulars and forms of application, which must be returned not later than the first post on Friday, September 17, 1926, may be obtained from the SECRETARY, Birkbeck College, Breams Buildings, Fetter Lane, E.C 4.

THE NATIONAL INSTITUTE OF POULTRY HUSBANDRY.

APPOINTMENT OF DIRECTOR.

Applications are invited for the above post. Scientific training and practical experience essential.

Particulars on application to the PRINCIPAL, Harper Adams Agricultural College, Newport, Shropshire.

August 28, 1926.

PARTNERSHIP.—Wanted, Analytical Chemist with capital, as active working partner in established London laboratory Another practice could be amalgamated therewith. Write "Z.T.589," c/o DEACONS, Fenchurch Avenue, E.C.3.

TRANSLATIONS of Scientific Subjects, from German, French, Russian and Polish, also Science literature research, at moderate prices. Box 4, c/o NATURE Office.

B.Sc., 1st class honours Botany (Mycology), subsidiary Chemistry, a years' research experience, desires post. Will accept a small salary. Box 151, c/o NATURE Office.

MACMILLAN'S NEW AND RECENT BOOKS.

ICE AGES, RECENT AND ANCIENT. By A. P. COLEMAN, M.A., Ph.D., F.R.S., Emeritus Professor of Geology, University of Toronto. With Illustrations and Maps. 8vo. 17s. net.

THE TIMES LITERARY SUPPLEMENT.—"Never before has such an array of glacial evidence been so skilfully mustered and marshalled. At last scientific workers have before them a graphic, succinct, and inspiring account of those wonderful vicissitudes of climate through which the world has passed since the dawn of its geological history—changes which have so profoundly influenced its scenery, and so greatly controlled the development and distribution of its plant and animal, including human, life."

CRYSTALLINE FORM AND CHEMICAL CONSTITUTION. By A. E. H. TUTTON, D.Sc., M.A.(Oxon), F.R.S., Past President of the Mineralogical Society, London; Author of "Crystallography and Practical Crystal Measurement." With 72 Illustrations. 8vo. 10s. 6d. net.

THE JOURNAL OF EDUCATION.—"A book for which the only adjective seems to be 'enthralling.' . . . The teacher who buys this book for his school science library will probably end by keeping it for himself."

THE FAMILIES OF FLOWERING PLANTS. I. DICOTYLEDONS. Arranged according to a New System based on their Probable Phylogeny. By J. HUTCHINSON, F.L.S., Assistant in the Herbarium, Royal Botanic Gardens, Kew. With Illustrations by W. E. TREVITHICK and the Author. 8vo. 20s. net. KEY TO THE FAMILIES OF THE DICOTYLEDONS. Reprinted from "The Families of Flowering Plants." 8vo. Manilla Cover. 2s. net.

THE PHYSIOLOGY OF THE CONTINUITY OF LIFE. By D. NOËL PATON, M.D., B.Sc., LL.D., F.R.S., Regius Professor of Physiology, University of Glasgow. With Illustrations. 8vo. 12s. net.

EVOLUTION. By J. GRAHAM KERR, F.R.S., Regius Professor of Zoology in the University of Glasgow. With 2 Plates in colour and 53 Illustrations in the Text. 8vo. 12s. net.

CONTEMPORARY REVIEW.—"Professor Graham Kerr has a charming prose style; he is a practical field naturalist of immense experience; he knows his own mind, and is not afraid to express quite bluntly his own views. He restates the Darwinian doctrine of natural selection, reinforced by Mendel's principles of heredity, by the insistence on the utility of particular characteristics amongst animals living freely, and by modern advances in physiological knowledge, with great power."

AN INTRODUCTION TO THE THEORY OF INFINITE SERIES. By T. J. I'a. BROMWICH, M.A., Sc.D., F.R.S., Fellow and Lecturer of St. John's College, Cambridge. Second Edition Revised with the assistance of T. M. MACROBERT, D.Sc., Lecturer in Mathematics in the University of Glasgow. 8vo. 30s. net.

NATURE.—"Not only to the mathematician is the book indispensable; it is also the best possible guide to any one who encounters mathematical analysis in his work. The second edition will increase the very high reputation gained by the first."

HIGHER MATHEMATICS FOR STUDENTS OF ENGINEERING AND SCIENCE. By FREDERICK G. W. BROWN, M.Sc.(London), F.C.P., Senior Mathematical Master, West Ham Secondary School. Crown 8vo. 10s.

EDUCATION.—"Everything in the book is well done. It shows that the author is a mathematical enthusiast and is bent on teaching mathematics in the proper way. . . . Mr. Brown has compiled a book that will be of inestimable service to many a teacher."

INTERMEDIATE MATHEMATICS (Analysis). By T. S. USHERWOOD, B.Sc., Wh.Ex., A.M.I.Mech.E., and C. J. A. TRIMBLE, M.A. Crown 8vo. 7s. 6d.

NATURE.—"The authors of this text-book on mathematics to the intermediate degree standard have already established a reputation by their previous works which is fully maintained in the present. The book is well planned."

DISCOVERY

A MONTHLY POPULAR JOURNAL OF KNOWLEDGE

Trustees: Sir J. J. Thomson, O.M., F.R.S., Sir F. G. Kenyon, K.C.B., F.B.A., Prof. A. C. Seward, Sc.D., F.R.S., Prof. R. S. Conway, Litt.D., F.B.A.

A *free* specimen copy of "Discovery" will be sent to anyone on request.

Contents of the September issue include:

WATER MITES. By Sir Arthur Shipley, G.B.E., F.R.S.

THE SLUG PEST: ITS PROBLEMS AND EXTERMINATION. By T. H. Taylor, M.A.

SULPHUR BACTERIA AND WATER POLLUTION. By Prof. David Ellis, D.Sc.

COMPOSITION OF THE UPPER AIR. By C. Britton, B.Sc.

Copies of the special July *Empire University Number* and the August *British Association Number*, to which Sir Oliver Lodge contributed, can still be obtained, each 1s. 2d. post free.

Illustrated. 1s. Monthly.
Annual Subscription 12s. 6d. post free.

BENN BROTHERS LTD.
154 Fleet Street, London, E.C.4

ANNOUNCEMENT.

Volume VIII. of *The Journal of General Physiology* will be a memorial to its founder, Dr. Jacques Loeb. This volume will contain papers by Dr. Loeb's pupils and his associates, together with a portrait and a sketch of his life. The volume will appear simultaneously with Volume IX. The publication of this volume began September 18, 1925.

Subscribers to the Journal, and others, may obtain the extra volume by sending their subscriptions (price $5.00) to

THE JOURNAL OF GENERAL PHYSIOLOGY,
AVENUE A AND 66TH ST., NEW YORK, N.Y.

ANNOUNCEMENT OF THE CONTENTS OF THE SEPTEMBER NUMBER OF THE

PHILOSOPHICAL MAGAZINE AND JOURNAL OF SCIENCE

Conducted by Sir OLIVER JOSEPH LODGE, D.Sc., LL.D., F.R.S.; Sir JOSEPH JOHN THOMSON, O.M., M.A., Sc.D., F.R.S.; JOHN JOLY, M.A., D.Sc., F.R.S., F.G.S.; RICHARD TAUNTON FRANCIS F.R.S.E.; and WILLIAM FRANCIS, F.L.S.

DOUBLE NUMBER. (254 *pages.*) *Price* ***10s. 6d.***

On the Condenser-Telephone. By G. Green, D.Sc.
Note on the High Frequency Oscillatory Discharge in Rarefied Gas. By R. C. Richards, M.Sc. (Plate VIII.)
On the Theory of the Absorption of X-Rays. By Dr. R. A. Houstoun.
The Magnetic Stability of Permanent Magnets. By Robert Cochrane Gray, M.A., D.Sc.
Absorption and Resonance Radiation in Excited Helium and the Structure of the 3889 Line. By W. H. McCurdy, Ph.D. (Plate IX.)
On the Determination of the Velocity Constant of a Unimolecular Reaction. By E. A. Guggenheim.
The Basis of Acoustic Measurements by Reverberation Methods. By A. H. Davis, D.Sc.
On the Effect of the Shape of the Cathode on the Glow Discharge. By W. Stephenson, M.Sc.
The Milner and Debye Theories of Strong Electrolytes. By George Scatchard.
The Milner and Debye Theories of Strong Electrolytes. By G. Nonhebel, B.A., and H. Hartley, M.A.
On a Geometrical Presentment of the Constants of an Elastic Material. By R. F. Gwyther, M.A.
Intensity Variations in the Spectrum of Neon. By Mary R. Johnson, M.Sc., and R. C. Johnson, B.A., Ph.D. (Plate X.)
Note on the Structure of Cadmium and Zinc Resonance Lines. By Prof. R. W. Wood. (Plate XI.)
The Fine Structure of Certain Lines and Energy Levels of Cadmium. By W. A. MacNair. (Plate XII.)
Note on some Observations of the Nitrogen Afterglow Spectra. By R. C. Johnson, B.A., Ph.D., and H. G. Jenkins, B.Sc.
On the Arc Spectrum of Lead. By Nalini Kanta Sur, M.Sc.
Scattered X-Rays. The J Phenomenon (Part IV.). By Prof. C. G. Barkla, F.R.S., and Dr. S. R. Khastgir.
The Compton Effect and the Reflexion of X-Rays by Crystals. By E. J. Williams, M.Sc.
Radiation produced by the Passage of Electricity through Gases. By Sir J. J. Thomson, O.M., F.R.S.
On Electric Double Refraction in Colloids. By Yngve Björnståhl. (Plate XIII.)
An Oscillographic Study of Anodic Polarization. By V. H. L. Searle, M.Sc.
A New Method of obtaining a Luminous Discharge in Gases at very Low Pressures. By Dr. F. Kirchner.
A New Method of obtaining a Luminous Discharge in Gases at very Low Pressures. By E. W. Gill and R. H. Donaldson.
The Water-Spark Absorption Spectrum of Iron. By A. K. Sur.
A New Method of producing a Discharge in Hydrogen. By R. Winstanley Lunt, M.Sc., Ph.D.
Proceedings of the Geological Society

With 6 Plates and numerous Illustrations in the Text.

Subscription for 1926, £4, including six double numbers, post free to any part of the world. Any double numbers issued beyond six charged extra.

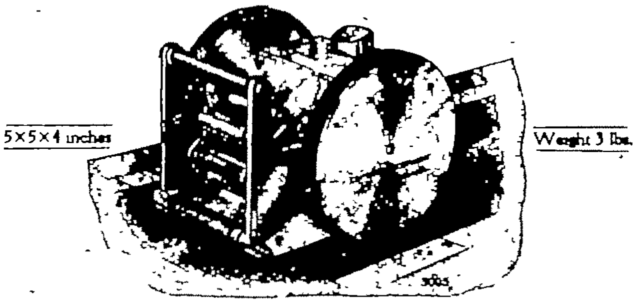
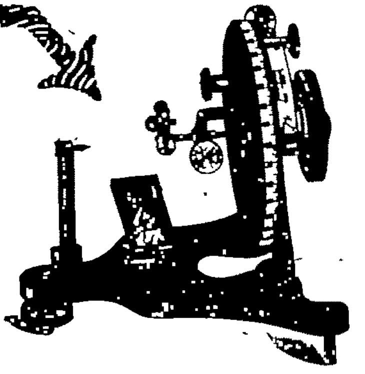
COTTON FIBRE ANALYSIS
is easily and quickly made with a
CAMBRIDGE COTTON SORTER



This instrument, designed by Dr. W. Lawrence Balls, analyses a sample of cotton fibres by distributing them on a collecting surface in order of their individual lengths: qualitative comparisons can then be made. A full description of the Cotton Sorter is given in List No. 138-N, which will be sent on request.

CAMBRIDGE
INSTRUMENT CO LTD
WORKS:- LONDON & CAMBRIDGE
Head Office & Showrooms:- 45, GROSVENOR PLACE LONDON, S.W.1
AMERICAN COMPANY:
Cambridge Instrument Co., Inc., Grand Central Terminal, New York

93



Constructed to the design of Dr. G. F. Herbert Smith, of the Mineral Department of the British Museum, and embodying many improvements over existing types.

THE STUDENT'S
GONIOMETER

The mirror is adjustable in any direction. The crystal holder and attachments facilitate the measurements of the crystal without readjustment, and a removable pointer is provided to ensure the adjustment into the axial line. The graduated circle of 5 inches (12·5 cm.) in diameter is fitted with a clamp and fine adjustment, and the silvered scale is divided to half degrees, reading by vernier to minutes of arc. £9 10 0

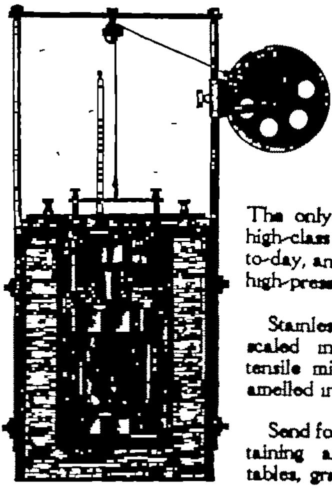
Established 1852.

THE
MAHLER-COOK
BOMB CALORIMETER



For determining the calorific value of Fuels (Coal, Coke, Oils, etc.).

The original Bomb Calorimeter, used all over the World and first introduced by the present makers in 1900. The only reliable, accurate, and high-class apparatus on the market to-day, and made by Engineers and high-pressure experts.

Stainless steel Bombs with descaled internal finish, or high tensile mild steel Bombs with enamelled interior.

Send for Illustrated Booklet containing all working instructions, tables, graphs, etc.

High Pressure Apparatus, Centrifuges, Microtomes, Electroscopes, Steam Meters, Electric Furnaces, etc.

London : J. & A. CHURCHILL, 7 Great Marlborough Street, W.1

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

DIVISION OF TROPICAL MEDICINE AND HYGIENE (UNIVERSITY OF LONDON).

Director—ANDREW BALFOUR, C.B., C.M.G., LL.D., M.D., D.P.H.

The School is open to fully qualified Medical Practitioners. Other applicants may be admitted in special circumstances.

There are two Courses of Study in each academic year, commencing in October and March respectively. Each Course lasts for 20 weeks inclusive of examinations. Certificates are granted to successful students in the School Examinations.

The Course consists of Laboratory and Clinical Work, Hygiene, and other Lectures and Demonstrations. It covers the work required for the D.T.M. & H.(Eng.), and part of that required for the M.D. in Tropical Medicine of the University of London.

Special Courses are held from time to time.

Four Research Studentships, each of the value of £250 per annum, and a Wandsworth Scholarship of £370 per annum, are available.

Full details are given in the Prospectus and Calendar, which may be obtained on application to the SECRETARY of the School, 23 Endsleigh Gardens, Euston Road, W.C.1.

BATTERSEA POLYTECHNIC,

LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

Head of Chemistry Department—JOSEPH KENYON, D.Sc., F.I.C.

CHEMICAL ENGINEERING.

H. GRIFFITHS, B.Sc., A.R.C.S., M.I.Chem.E.,
and H. HUNTER, D.Sc., F.I.C., A.Inst.P.

(September to Easter—50 meetings.)

Lectures—Monday, 7.15 to 9.30 P.M.

Laboratory—Friday, 7 to 9.45 P.M.

Course commences on September 27, 1926.

Fee 20s. for London, Kent, or Middlesex students.

The Course is suitable for Science Graduates and persons with works experience. The syllabus is made to depend on the requirements and experience of the students, and the facilities include access to a semi-scale laboratory.

Particulars of all classes gratis on application to the PRINCIPAL.

UNION OF SOUTH AFRICA.

WITWATERSRAND TECHNICAL INSTITUTE.

Applications are invited for the vacancy for the HEAD OF THE DEPARTMENT OF CHEMISTRY.

SALARY.—Salary £450-£25-£650, plus Local Allowance, which, in the case of married officers, brings the total emoluments from £516 to £726. The initial salary will be fixed according to the existing salary, qualifications and experience of the successful applicant.

ENGAGEMENT.—The appointment will be made subject to the conditions of service laid down in the Union Higher Education Act, 1923, which may be inspected in this office.

QUALIFICATIONS.—Applicants must be qualified chemists, and the possession of qualifications of the Pharmaceutical Society of Great Britain and knowledge of Metallurgy would be a recommendation. The possession of degrees or equivalent professional qualifications and/or teaching and practical experience will be considered in making the appointment.

DUTIES.—The post is a full-time one and includes both day and evening work, and the successful applicant will be required to take charge of the School of Pharmacy in addition to undertaking lectures in various branches of Chemistry.

Applications and copies of testimonials containing information as to the particulars of training, experience and present salary should be lodged with the SECRETARY, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2, from whom the prescribed forms of application may be obtained, not later than September 30.

COUNTY BOROUGH OF WEST HAM.

ESSEX MUSEUM OF NATURAL HISTORY,

ROMFORD ROAD, STRATFORD, E.15.

Applications are invited for the position of full-time ASSISTANT in the Museum from persons having a practical knowledge of Museum Work.

Applicants should have had some Biological training, and must be experienced in Taxidermy and be able to mount and set up specimens and prepare dissections for exhibition, and should be capable of preparing diagram drawings and taking photographs to illustrate exhibits.

The possession of a Science Degree of a British University, although desirable, will not be considered essential if other qualifications are satisfactory.

The salary will be at the rate of £150 per annum plus Civil Service Award. Applicants must be members of a recognised Professional Association.

Applications to be sent by September 30, 1926, to the PRINCIPAL of the West Ham Municipal College, Romford Road, E.15, from whom particulars and forms of application may be obtained.

September 1, 1926.

GEORGE E. HILLEARY,
Town Clerk.

A EUROPEAN SCIENCE MASTER is required for the Agricultural School at Moor Plantation, Ibadan, Nigeria. Candidates should be of good health, between 25 and 35 years of age, and should possess the Teaching Certificate of the Board of Education or the Scottish Education Department. They should be able to teach Mathematics, Chemistry, Physics and Botany to about Junior Local standard. Ability to teach elementary Surveying would be an additional qualification. Further information and forms of application are obtainable from the SECRETARY, C.A. (N.), Board of Education, Whitehall, London, S.W.1. Scottish candidates should apply to the SECRETARY, Scottish Education Department, S.E.D. (N.), Whitehall, London, S.W.1. List of applications closes September 27.

THE NATIONAL INSTITUTE OF POULTRY HUSBANDRY.

APPOINTMENT OF DIRECTOR.

Applications are invited for the above post. Scientific training and practical experience essential.

Particulars on application to the PRINCIPAL, Harper Adams Agricultural College, Newport, Shropshire.

August 28, 1926.

RESEARCH CHEMISTS are required for the CHEMICAL RESEARCH LABORATORY, Teddington, Middlesex. Candidates must possess a good Honours degree in Chemistry or equivalent qualifications, and some research experience. Scale of salary £175-£15-£235, plus Civil Service bonus. Bonus is at present approximately £91 on £175. Superannuation provision will be made under the Federated Superannuation System for Universities.

Preference will be given, other things being equal, to ex-Service men.

Applications should be made on a form to be obtained from the SECRETARY, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1, and must be received not later than October 7, 1926.

WANTED — ASTRONOMICAL TELESCOPE, 4½" or 5" Zeiss or Cooke. Full particulars. Also 2½". MORRIS, 7 Spencer Street, Leamington Spa.

RHEINBERG MICROMETERS and other GRATICULES by the processes of Grainless and of Filmless Photography. Stock list of standard articles on request. RHEINBERGS & Co., 57-60 Holborn Viaduct, London, E.C.1.

POLARIMETER or SACCHARIMETER, new or second-hand, required complete and in good condition, suitable for Sugar Beet Analysis. RIDEOUT, 9 Rodney Street, Liverpool.

TEST ROOM ASSISTANT WANTED, familiar with principles and construction of Physical apparatus. Apply in writing, with full particulars of qualifications and experience, to JOHN J. GRIFFIN & SONS, LTD., Kemble Street, London, W.C.2.

The issues for May 29 and July 3, containing, respectively, Supplements by Prof. T. M. Lowry (on "Electrons, Atoms and Molecules") and Dr. G. E. Hale (on "Some New Possibilities in Solar Research"), can still be supplied.

Office of NATURE, St. Martin's Street, W.C.2

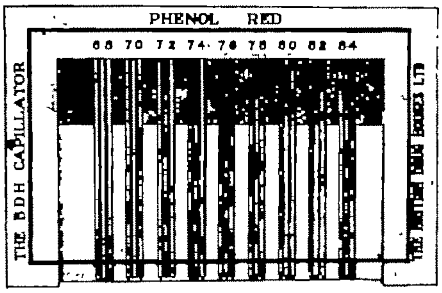
B.D.H. CAPILLATOR

THE B.D.H. "Capillator" provides an improved method for the colorimetric determination of Hydrogen Ion Concentration.

The "Capillator" consists of a series of capillary tubes filled with buffer solutions containing an indicator. These tubes are mounted in threes on a white card, and form a series of coloured strips, each strip being marked with its exact PH value. Each card illustrates the complete colour change of the indicator.



A determination of PH is carried out by mixing equal quantities of liquid and indicator, and comparing the colour produced with that of the standard tubes of the "Capillator." By means of the "Capillator" determinations of PH are carried out expeditiously and accurately, and as little as one drop of the liquid will suffice for a test

Prices and further particulars will be supplied on application.

MACMILLAN'S NEW AND RECENT BOOKS.

THE FAMILIES OF FLOWERING PLANTS. I. DICOTYLEDONS. Arranged according to a New System based on their Probable Phylogeny. By J. HUTCHINSON, F.L.S., Assistant in the Herbarium, Royal Botanic Gardens, Kew. With Illustrations by W. E. TREVITHICK and the Author. 8vo. 20s. net. KEY TO THE FAMILIES OF THE DICOTYLEDONS. Reprinted from "The Families of Flowering Plants." 8vo. Manilla Cover. 2s. net.

THE PHYSIOLOGY OF THE CONTINUITY OF LIFE. By D. NOËL PATON, M.D., B.Sc., LL.D., F.R.S., Regius Professor of Physiology, University of Glasgow. With Illustrations. 8vo. 12s. net.

EVOLUTION. By J. GRAHAM KERR, F.R.S., Regius Professor of Zoology in the University of Glasgow. With 2 Plates in colour and 53 Illustrations in the Text. 8vo. 12s. net.

CONTEMPORARY REVIEW.—"Professor Graham Kerr has a charming prose style; he is a practical field naturalist of immense experience; he knows his own mind, and is not afraid to express quite bluntly his own views. He restates the Darwinian doctrine of natural selection, reinforced by Mendel's principles of heredity, by the insistence on the utility of particular characteristics amongst animals living freely, and by modern advances in physiological knowledge, with great power."

ICE AGES, RECENT AND ANCIENT. By A. P. COLEMAN, M.A., Ph.D., F.R.S., Emeritus Professor of Geology, University of Toronto. With Illustrations and Maps. 8vo. 17s. net.

THE TIMES LITERARY SUPPLEMENT.—"Never before has such an array of glacial evidence been so skilfully mustered and marshalled. At last scientific workers have before them a graphic, succinct, and inspiring account of those wonderful vicissitudes of climate through which the world has passed since the dawn of its geological history—changes which have so profoundly influenced its scenery, and so greatly controlled the development and distribution of its plant and animal, including human, life."

CRYSTALLINE FORM AND CHEMICAL CONSTITUTION. By A. E. H. TUTTON, D.Sc., M.A.(Oxon), F.R.S., Past President of the Mineralogical Society, London; Author of "Crystallography and Practical Crystal Measurement." With 72 Illustrations. 8vo. 10s. 6d. net.

THE JOURNAL OF EDUCATION.—"A book for which the only adjective seems to be 'enthralling.' . . . The teacher who buys this book for his school science library will probably end by keeping it for himself."

AN INTRODUCTION TO THE THEORY OF INFINITE SERIES. By T. J. I'a. BROMWICH, M.A., Sc.D., F.R.S., Fellow and Lecturer of St. John's College, Cambridge. Second Edition Revised with the assistance of T. M. MACROBERT, D.Sc., Lecturer in Mathematics in the University of Glasgow. 8vo. 30s. net.

NATURE.—"Not only to the mathematician is the book indispensable; it is also the best possible guide to any one who encounters mathematical analysis in his work. The second edition will increase the very high reputation gained by the first."

HIGHER MATHEMATICS FOR STUDENTS OF ENGINEERING AND SCIENCE. By FREDERICK G. W. BROWN, M.Sc.(London), F.C.P., Senior Mathematical Master, West Ham Secondary School. Crown 8vo. 10s.

EDUCATION.—"Everything in the book is well done. It shows that the author is a mathematical enthusiast and is bent on teaching mathematics in the proper way. . . . Mr. Brown has compiled a book that will be of inestimable service to many a teacher."

INTERMEDIATE MATHEMATICS (Analysis). By T. S. USHERWOOD, B.Sc., Wh.Ex., A.M.I.Mech.E., and C. J. A. TRIMBLE, M.A. Crown 8vo. 7s. 6d.

NATURE.—"The authors of this text-book on mathematics to the intermediate degree standard have already established a reputation by their previous works which is fully maintained in the present. The book is well planned."

PRICE - £15 15 0

Authoritative Reviews:

"This encyclopædic work differs from many that have preceded it in that it is produced by those who have worked strenuously and successfully to promote knowledge. Originality of treatment and masterly handling are everywhere exhibited."—*Engineering.* (Vol. 1.)

"A book which every electrical engineer ought to possess. . . . A mine of information in a field which, at present, is not adequately covered by any one work."—*The Electrician.* (Vol. 2.)

"As a summary of our present knowledge of certain aspects of meteorology, the work is of great value. It will perhaps be regarded in future as a milestone showing the stage reached by the science at the end of the great war."—*The Meteorological Magazine.* (Vol. 3.)

SOTHERAN'S CATALOGUE OF SCIENCE AND TECHNOLOGY.

Already published. Part I: Sets of Scientific Periodicals, General and Collected Works (pp. 80). Part II: Mathematics (pp. 128). Part III: Astronomy, Geodesy, Chronology, Horology, and Dialling (pp. 112). Part IV: Physics, Letters A-R (pp. 112). Part V: Physics, Letters S-Z, and Supplement (pp. 56). Part VI: Geology, Meteorology and Physical Geography, Mineralogy and Crystallography; Microscopy (pp. 144). Just published: Part VII: Chemistry and Chemical Technology (pp. 208). In preparation: Part VIII: Mining and Metallurgy.

"This special catalogue of Messrs. Sotheran needs no recommendation, being well known for its valuable bibliographic notes, and the number of choice and rare books offered for sale."
NATURE.

Messrs. Sotheran are always ready to buy libraries or smaller collections of books on exact science, as well as sets of scientific periodicals. They invite correspondence in connexion with books rare and difficult to get.

HENRY SOTHERAN & CO.,
140 Strand, W.C.2, and 43 Piccadilly, W.1, London.

That Book you want!

Foyles can supply any Scientific Book that is in print and most of those that are out of print. They have a Special Department for this class of literature under a Manager who has experience and knowledge of the Natural Sciences. Call and consult him, or write and you will get an intelligent reply. Books sent on approval. Over a million volumes Second-hand and New on every conceivable subject in stock. Twenty-one Departmental Catalogues issued, any of which will be sent gratis and post free on mentioning interests.

That Book you do not want!

Foyles will buy it.—A single volume to a library.

Expert valuers sent any distance.

FOYLES, 121 Charing Cross Road, London.

¶ **W. HEFFER & SONS, Ltd., 4 PETTY CURY, CAMBRIDGE,** will be glad to receive offers of Complete Libraries, Sets of Journals, and Smaller Collections of Books, for which they are prepared to offer full current value and pay cash.

¶ They have a very highly organised department for the supply to Librarians, Institutions, and others, of Scientific Books and Journals, both English and Foreign (new and second-hand).

¶ CATALOGUE 269. Scientific Books and Publications of learned Societies.

Licensed Valuers for Probate.

MESSRS. RIVINGTON'S LIST

ELEMENTARY CALCULUS.

By C. H. P. MAYO, M.A., Formerly Senior Mathematical Master at Harrow School. Crown 8vo. With numerous Diagrams. 10s.

CONTENTS. Definitions and Limits. Differential Coefficients—The Use of a Differential Coefficient—Maxima and Minima Values—The Functional Notation—A Function of a Function—Circular Measure—Polar Co-ordinates—Second and Higher Differential Coefficients—Further Considerations of Maxima and Minima Values—Small Errors and Approximations in Measuring—The Differential of an Arc of a Curve—Curve Tracing—Rolle's Theorem—Application of the Integral Calculus to Physical Problems—Reduction of Integral to Standard Forms—The Length of an Arc of a Curve—Solids of Revolution—Successive Integration—Differential Equations—Cusps, etc.

PLANE GEOMETRY FOR SCHOOLS

By T. A. BECKETT, M.A., and F. E. ROBINSON, M.A., Mathematical Masters at St. Paul's School. In Two Parts. Crown 8vo. 5s. each.

CONTENTS: Part I.—Straight lines, angles, triangles, parallelograms, circles, areas, Pythagoras's theorem and constructions arising therefrom, co-ordinates, and easy trigonometry. Part II.—Harder properties of areas, extension of Pythagoras's theorem, rectangle properties of the circle, radical axis, propositions on inequalities, maxima and minima, and regular polygons, ratio and proportion. Numerous examples.

SOLID GEOMETRY, INCLUDING THE MENSURATION OF SURFACES AND SOLIDS.

By R. S. HEATH, D.Sc., Formerly Professor of Mathematics and Vice-Principal of the University of Birmingham. Fifth Edition, Enlarged. Crown 8vo. 4s.

SCHOOL STATICS.

By W. G. BORCHARDT, M.A., B.Sc. Crown 8vo. With or without Answers, 7s. 6d.

SCHOOL DYNAMICS.

By W. G. BORCHARDT, M.A., B.Sc. Crown 8vo. With or without Answers, 7s. 6d.

COMMERCIAL ARITHMETIC.

By W. G. BORCHARDT, M.A., B.Sc. Crown 8vo. With Answers, 3s. 6d.

A SYSTEMATIC COURSE OF PRACTICAL SCIENCE FOR SECONDARY AND OTHER SCHOOLS.

By ARTHUR W. MASON, B.Sc., B.A. (Lond.), Headmaster of the Grammar School, Tadcaster. Small Quarto. With numerous Diagrams.

BOOK I. INTRODUCTORY PHYSICAL MEASUREMENTS. Forming a First Year Course in Physics. 2s. 6d.

BOOK II. EXPERIMENTAL HEAT. Dealing with all those parts of HEAT usually taken in a school course up to the standard of the Matriculation and Senior Local Examinations. 3s.

PRACTICAL EXPERIMENTS IN HEAT AND LIGHT, CONTAINING OVER 120 TYPICAL EXPERIMENTS.

By W. ST. B. GRIFFITH, B.A., B.Sc., and P. T. PETRIE, M.Sc., A.M.I.C.E. Crown 8vo. With Diagrams. One Vol., 4s. 6d.; or in Two Parts—**Heat, 2s. 6d. Light, 2s. 6d.**

A FIRST AND SECOND YEARS' COURSE OF PRACTICAL CHEMISTRY.

By GEORGE H. MARTIN, M.A., F.C.S., and ELLIS JONES, M.A., Science Masters, Bradford Grammar School. Quarto. 2s. 6d. each.

AN INTRODUCTION TO PRACTICAL QUANTITATIVE ANALYSIS.

By H. P. HIGHTON, M.A., Late Assistant Master at Rugby School. With Diagrams. Crown 8vo. 4s.

AN INTRODUCTION TO QUALITATIVE ANALYSIS.

By H. P. HIGHTON, M.A. With Diagrams. Crown 8vo. 4s.

RIVINGTONS, 34 King Street, Covent Garden, London.

MACMILLAN'S NEW AND RECENT BOOKS.

COTTON AND ITS PRODUCTION. By W. H. JOHNSON, lately Agricultural Adviser to the Australian Cotton Growing Association. With an Introduction by SIR WYNDHAM DUNSTAN, F.R.S., and a Foreword by SIR WILLIAM HIMBURY, Managing Director of the British Cotton Growing Association. With 26 Maps showing the Cotton Areas of the World. Med. 8vo. 30s. net.

RITUAL AND BELIEF IN MOROCCO. By EDWARD WESTERMARCK, Ph.D., author of "The History of Human Marriage," etc Illustrated. 2 vols. 8vo. 50s. net.

This work is a systematic account of the popular religion and magic of the Muhammadan natives of Morocco based on seven years' experience among them.

ORIGINS OF EDUCATION AMONG PRIMITIVE PEOPLES. A Comparative Study in Racial Development. By W. D. HAMBLY, B.Sc., Anthropologist in the Wellcome Expedition in the Sudan, Assistant Curator, African Ethnology, Field Museum, Chicago. With a Preface by DR. CHARLES HOSE, of Sarawak. With 74 pages of Illustrations in half-tone and line. 8vo. 25s. net.

The aim of this work is to make an historical and regional survey of customs of primitive races with special reference to moral, religious, physical, and social education, in so far as it has been developed without intrusion of European influences.

CRYSTALLINE FORM AND CHEMICAL CONSTITUTION. By A. E. H. TUTTON, D.Sc., M.A.(Oxon), F.R.S., Past President of the Mineralogical Society, London; Author of "Crystallography and Practical Crystal Measurement." With 72 Illustrations. 8vo. 10s. 6d. net.

THE MINERALOGICAL MAGAZINE.—"The book is well printed and illustrated, and it gives a very clear and readable account of the subject. It should be seen by all students of chemistry as well as those of crystallography."

THE FAMILIES OF FLOWERING PLANTS. I. DICOTYLEDONS. Arranged according to a New System based on their Probable Phylogeny. By J. HUTCHINSON, F.L.S., Assistant in the Herbarium, Royal Botanic Gardens, Kew. With Illustrations by W. E. TREVITHICK and the Author. 8vo. 20s. net. KEY TO THE FAMILIES OF THE DICOTYLEDONS. Reprinted from "The Families of Flowering Plants." 8vo. Manilla Cover. 2s. net.

THE PHYSIOLOGY OF THE CONTINUITY OF LIFE. By D. NOËL PATON, M.D., B.Sc., LL.D., F.R.S., Regius Professor of Physiology, University of Glasgow. With Illustrations. 8vo. 12s. net.

EVOLUTION. By J. GRAHAM KERR, F.R.S., Regius Professor of Zoology in the University of Glasgow. With 2 Plates in colour and 53 Illustrations in the Text. 8vo. 12s. net.

DISCOVERY.—"It is altogether a good book far and above the average, and besides its theme of evolution it has a valuable secondary characteristic. It is a sound guide to really scientific thinking and a valuable corrective to some of the cheap 'scientific' posing of to-day. Heartily commended for general reading as well as to those interested."

HIGHER MATHEMATICS FOR STUDENTS OF ENGINEERING AND SCIENCE. By FREDERICK G. W. BROWN, M.Sc.(London), F.C.P., Senior Mathematical Master, West Ham Secondary School. Crown 8vo. 10s.

NATURE.—"This work embodies those branches of pure mathematics required by senior engineering students up to degree standard and it covers the field very adequately. . . . For an attempt to return from the monograph to the 'comprehensive' type of book it is eminently successful, and the numerous examples are well chosen with the correct practical bias . . . A really useful book."

MACMILLAN & CO., LTD., LONDON, W.C.2.

Just Published. Volume VIII. of the New Edition of

CHAMBERS'S

ENCYCLOPÆDIA

A Dictionary of Universal Knowledge.

Edited by DAVID PATRICK, LL.D., and WILLIAM GEDDIE, M.A., B.Sc.

To be completed in 10 Vols., Imp. 8vo. Cloth, 20/- net; half-moro., 35/- net per vol.

Chambers's Encyclopædia has a character of its own. It strives to be at once comprehensive, compact, accurate, lucid, readable, and handy for reference. The larger themes are broken up into many articles; but provision is throughout made for securing a systematic conspectus of the whole subject. Thus the article GEOLOGY gives a history of the science and plans out the whole field; while the reader in search of information on single items such as Plesiosaurus, Boulder-Clay, Denudation, Caves, Pitchstone, Greensand, Mammoth, Coprolites, Dykes, Trilobites, Pterodactyl, the Antiquity of Man, will not have to hunt for these hidden in a trackless wilderness of continuous dissertation, but will find each under its several head

Some Contributors whose Articles appear in the New Edition:

J. W. Mackail.
Lascelles Abercrombie.
Lord Riddell.
Sir Stanley Chapman, K.C.B.
Northcote W. Thomas
Lord Birkenhead.
George Bernard Shaw.
G. K. Chesterton.

SCIENTIFIC AND EDUCATIONAL
BOOKSELLERS

ENQUIRIES BY LETTER
RECEIVE IMMEDIATE ATTENTION

86 Charing Cross Road, London, W.C.2

¶ W. HEFFER & SONS, Ltd., 4 PETTY CURY, CAMBRIDGE, will be glad to receive offers of Complete Libraries, Sets of Journals, and Smaller Collections of Books, for which they are prepared to offer full current value and pay cash.

¶ They have a very highly organised department for the supply to Librarians, Institutions, and others, of Scientific Books and Journals, both English and Foreign (new and second-hand).

¶ CATALOGUE 269. Scientific Books and Publications of learned Societies.

Licensed Valuers for Probate.

Telegrams and Cables: HEFFER, CAMBRIDGE. Telephone. [illegible] (2 lines).

CHEMICAL AND TECHNICAL BOOKS

We carry a very large stock both Second-hand and New in all departments of Technology, and can quote the best terms

Write for Catalogue—

WILLIAM BRYCE, Scientific Bookseller,
54-54a Lothian Street, EDINBURGH.

NOTICE.

Copies of NATURE for May 29 and July 3, containing, respectively, Supplements by Prof. T. M. Lowry (on "Electrons, Atoms and Molecules") and Dr. G. E. Hale (on "Some New Possibilities in Solar Research"), can still be supplied at published price, plus postage.

St. Martin's Street, London, W.C.2.

SOTHERAN'S CATALOGUE OF SCIENCE AND TECHNOLOGY.

Already published. Part I: Sets of Scientific Periodicals, General and Collected Works (pp. 80). Part II: Mathematics (pp. 128). Part III: Astronomy, Geodesy, Chronology, Horology, and Dialling (pp. 112). Part IV: Physics, Letters A-R (pp. 112). Part V: Physics, Letters S-Z, and Supplement (pp. 56). Part VI: Geology, Meteorology and Physical Geography, Mineralogy and Crystallography; Microscopy (pp. 144). Just published: Part VII: Chemistry and Chemical Technology (pp. 208). In preparation: Part VIII: Mining and Metallurgy.

"This special catalogue of Messrs. Sotheran needs no recommendation, being well known for its valuable bibliographic notes, and the number of choice and rare books offered for sale."
NATURE.

Messrs. Sotheran are always ready to buy libraries or smaller collections of books on exact science, as well as sets of scientific periodicals. They invite correspondence in connection with books rare and difficult to get.

HENRY SOTHERAN & CO.,
140 Strand, W.C.2, and 43 Piccadilly, W.1, London.

That Book you want!

Foyles can supply any Scientific Book that is in print and most of those that are out of print. They have a Special Department for this class of literature under a Manager who has experience and knowledge of the Natural Sciences. Call and consult him, or write and you will get an intelligent reply. Books sent on approval. Over a million volumes Second-hand and New on every conceivable subject in stock. Twenty-one Departmental Catalogues issued, any of which will be sent gratis and post free on mentioning interests.

That Book you do not want!

Foyles will buy it.—A single volume to a library.

Expert valuers sent any distance.

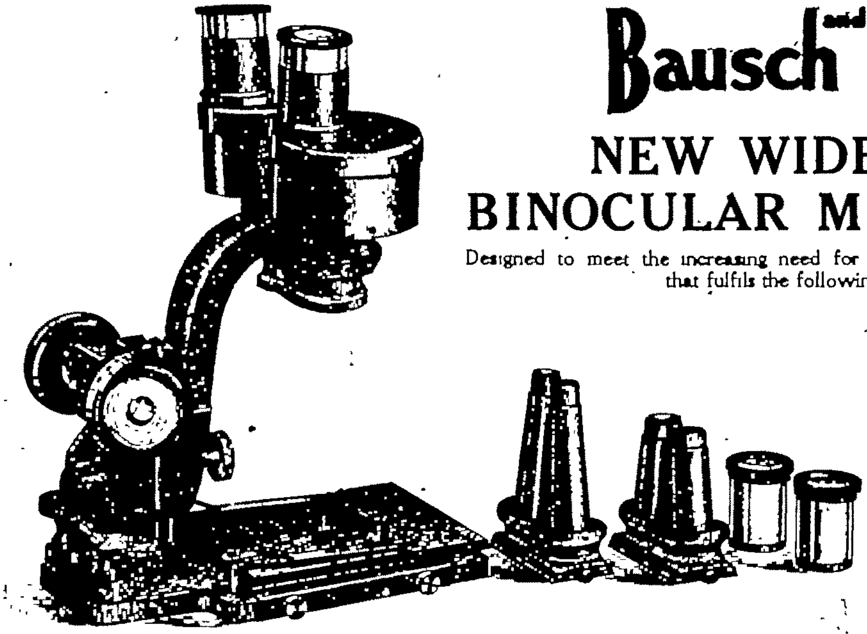
Bausch and Lomb

NEW WIDE FIELD BINOCULAR MICROSCOPE



Designed to meet the increasing need for a high grade binocular microscope that fulfils the following conditions:

1. Stereoscopic Vision.
2. Extremely Large Field.
3. Long Working Distance.
4. High Eye Point.
5. Wide Range of Magnification.

It gives the advantage of viewing the image in its true position, not inverted or reversed.

Supplied on four different stands covering every requirement, the microscope bei g interchangeable on each stand.

Illustrated descriptive list sent on request.

Also Microscopes for all purposes, Microtomes, Photomicrographic Apparatus, Centrifuges, Colorimeters, Hæmoglobinometers, Balopticon Projection Lanterns, etc.

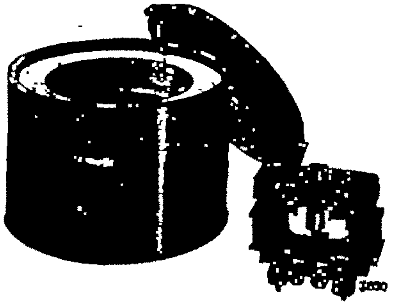
SCHERING VIBRATION GALVANOMETER



Size = 22 × 21 × 15 cm.

This galvanometer is particularly suitable for use in conjunction with the Schering Bridge method of measuring power losses in dielectrics, and for precision measurements on standard condensers. It may be tuned from a distance by varying the intensity of a D.C. electromagnetic field. The movement is protected from external magnetic fields by a laminated shield (shown on the left of the illustration). The instrument is robust, and has low capacity.

APPROXIMATE SENSITIVITY DATA
for a galvanometer having a frequency range of 25 to 120 cycles per second.

Resistance at 20° C.		Period (without magnetic control)	Deflection per microamp. at 1 m.		Magnetising current for 50 cycles.
D.C. polarising windings	A.C. winding		25~	120~	
112 ohms.	250 ohms.	0.05 second.	48 mm.	13 mm	0.09 amp.

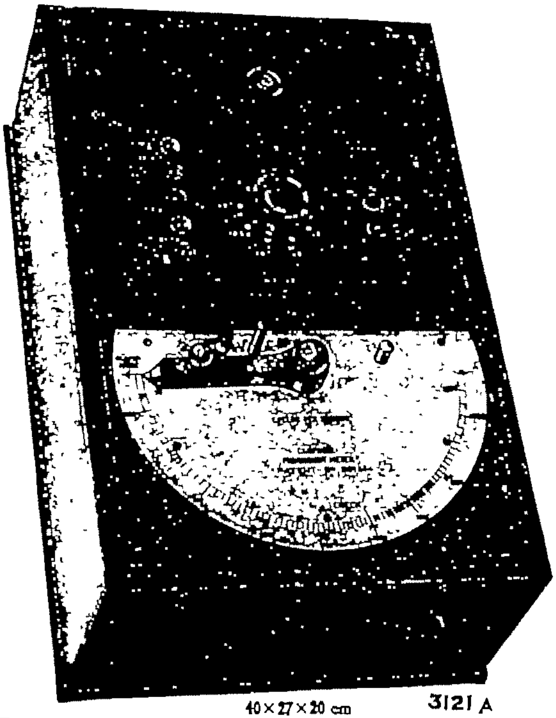
—CAMPBELL FREQUENCY METER—



47 40 × 27 × 20 cm 3121 A

This instrument, designed by Mr. Albert Campbell, measures acoustic frequencies from about 18 to 4000 cycles, the accuracy being such that at 1000 cycles readings may be taken to within 0·1 per cent. The instrument is portable and convenient to use. Further particulars are given in List No. 170-N.

MANUFACTURE OF SCIENTIFIC INSTRUMENTS

We have recently installed new machinery in our workshops, and are prepared to undertake the manufacture of new instruments to special design. We have a large selection of school microscopes suitable for educational purposes, workshop microscopes suitable for industrial use, microscope lamps, and special microscopical accessories, all of which are manufactured in our own workshops.

REPAIRS TO SCIENTIFIC INSTRUMENTS

Our facilities for carrying out all kinds of repairs to scientific instruments having been increased, we are now able to undertake additional work, and to carry out the repairs in a shorter time than hitherto. Our men are highly skilled mechanics, of long experience in this type of work, and produce results of the highest quality.

Catalogues and Estimates

Catalogues will be sent post free on request, and estimates are submitted free of cost.

Microscopes—Microtomes—Dark Ground Condensers—Photomicrographic Apparatus—Hæmatological Appliances—Dissecting Stands and Lenses—Microscopical, Medical and Dental Illuminating Apparatus—Micro-projection Apparatus—Epidiascopes—Colorimeters—Prismatic Field Glasses—Cameras, &c.

ZENITH

NOTICE

We beg to inform our customers and suppliers that the business formerly carried on as THE ZENITH MANUFACTURING COMPANY has now been incorporated as a private company under the title of

THE ZENITH ELECTRIC COMPANY, LIMITED,

in order to provide additional capital and manufacturing facilities to cope with the increased demand for our well-known "ZENITH" electrical products.

Provision has been made for the collection by the new company of all accounts and the discharge by them of all liabilities in connection with the business, which will be continued without interruption under the same management, but the new title as above.

The directors trust that the happy relationship which has subsisted in the past will continue under the new proprietary.

THE ZENITH ELECTRIC CO. LTD.
Contractors to H.M. Admiralty, War Office, Air Ministry, Post Office, L.C.C., etc.

MACMILLAN'S NEW AND RECENT BOOKS.

IN UNKNOWN ARABIA. By MAJOR R. E. CHEESMAN, O.B.E., F.R.G.S., His Majesty's Consul in North-west Abyssinia. With a Foreword by MAJOR-GENERAL SIR PERCY Z. COX, G.C.M.G. With 32 pages of Illustrations in half-tone and 3 Maps and Plans Super Royal 8vo. 25s. net.

COTTON AND ITS PRODUCTION. By W. H. JOHNSON, lately Agricultural Adviser to the Australian Cotton Growing Association. With an Introduction by SIR WYNDHAM DUNSTAN, F.R.S., and a Foreword by SIR WILLIAM HIMBURY, Managing Director of the British Cotton Growing Association. With 26 Maps showing the Cotton Areas of the World. Med. 8vo. 30s. net.

Sir Wyndham Dunstan in his Introduction says, "Mr. Johnson explains the present position and prospects of cotton cultivation in every country in which there is any chance of success, and his book furnishes the most complete guide and encyclopædia which has yet appeared."

HOLISM AND EVOLUTION. By GENERAL THE RIGHT HON. J. C. SMUTS. 8vo. 18s. net.

The work deals with some of the problems which fall within the debateable borderland between Science and Philosophy; and may be expected to attract considerable attention in view of recent advances in physical and biological science.

RITUAL AND BELIEF IN MOROCCO. By EDWARD WESTERMARCK, Ph.D., author of "The History of Human Marriage," etc. Illustrated. 2 vols. 8vo. 50s. net.

This work is a systematic account of the popular religion and magic of the Muhammadan natives of Morocco based on seven years' experience among them.

THE AO NAGAS. By J. P. MILLS, I.C.S., author of "The Lhota Nagas." With a Foreword by HENRY BALFOUR, F.R.S., and Supplementary Notes and Bibliography by DR. J. H. HUTTON, C.I.E. With 34 pages of Illustrations in half-tone and line, and 2 Maps. 8vo. 30s. net.

ORIGINS OF EDUCATION AMONG PRIMITIVE PEOPLES. A Comparative Study in Racial Development By W. D. HAMBLY, B.Sc., Anthropologist for the Wellcome Expedition to the Sudan, Assistant Curator, African Ethnology, Field Museum, Chicago. With a Preface by DR. CHARLES HOSE (of Sarawak). With 74 pages of Illustrations in half-tone and line. 8vo. 25s. net.

CRYSTALLINE FORM AND CHEMICAL CONSTITUTION. By A. E. H. TUTTON, D.Sc., M.A.(Oxon), F.R.S., Past President of the Mineralogical Society, London; Author of "Crystallography and Practical Crystal Measurement." With 72 Illustrations. 8vo. 10s. 6d. net.

THE MINERALOGICAL MAGAZINE.—"The book is well printed and illustrated, and it gives a very clear and readable account of the subject. It should be seen by all students of chemistry as well as those of crystallography."

THE PHYSIOLOGY OF THE CONTINUITY OF LIFE. By D. NOËL PATON, M.D., B.Sc., LL.D., F.R.S., Regius Professor of Physiology, University of Glasgow. With Illustrations. 8vo. 12s. net.

JOURNAL OF EDUCATION.—"This is an important contribution to biological literature, and should be read and carefully considered by all interested in the current theory of heredity and in advanced cytological research."

MEMORIAL LECTURES ON EMINENT CHEMISTS

Delivered before the CHEMICAL SOCIETY.

Volume I. (Reproduced by a photolithographic process.) 592 pp. Illustrated. Price **10s. 6d.**, postage 9d extra.

CONTENTS

1. The Stas Memorial Lecture. By J. W. MALLET, F.R.S.
2. The Kopp Memorial Lecture. By Sir EDWARD THORPE, C.B., D.Sc., F.R.S.
3. The Marignac Memorial Lecture. By P. T. CLEVE.
4. The Hofmann Memorial Lecture. By the Rt. Hon. Lord PLAYFAIR, G.C.B., F.R.S.; Sir FREDERICK A. ABEL, Bt., K.C.B., G.C.V.O., F.R.S.; Sir WILLIAM PERKIN, LL.D., F.R S.; H. E. ARMSTRONG, LL.D., F.R.S.
5. The Helmholtz Memorial Lecture. By G. F. FITZGERALD, M.A., D.Sc., F.R.S.
6. The Lothar Meyer Memorial Lecture. By P. P. BEDSON, M.A., D.Sc.
7. The Pasteur Memorial Lecture. By PERCY F. FRANKLAND, C.B.E., LL.D., F.R.S.
8. The Kekulé Memorial Lecture. By F. R. JAPP, M.A., LL.D., F.R.S.
9. The Victor Meyer Memorial Lecture. By Sir EDWARD THORPE, C.B., D Sc., F.R.S.
10. The Bunsen Memorial Lecture. By the Rt. Hon. Sir HENRY E. ROSCOE, LL.D., D.Sc., F.R.S.
11. The Friedel Memorial Lecture. By J. M. CRAFTS.
12. The Nilson Memorial Lecture. By O. PETTERSSON.

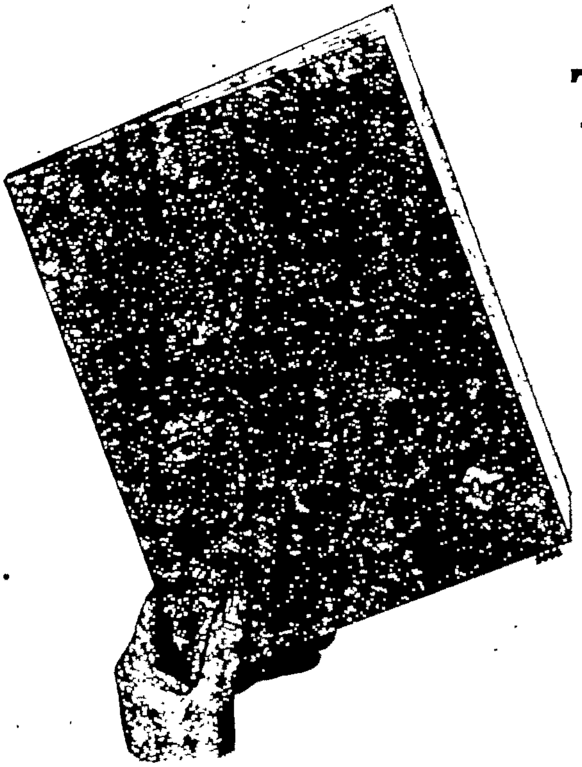
Volume II. 297 pp. Illustrated. Price **8s.**, postage extra. At Home 6d., Abroad 9d.

CONTENTS

13. The Rammelsberg Memorial Lecture. By Sir HENRY A. MIERS, D.Sc., LL.D., F.R.S.
14. The Raoult Memorial Lecture. By J. H VAN 'T HOFF, F.R.S.
15. The Wislicenus Memorial Lecture. By W. H. PERKIN, Sc.D., LL.D., F.R.S.
16. The Cleve Memorial Lecture. By Sir EDWARD THORPE, C.B., D.Sc., F.R.S.
17. The Wolcott Gibbs Memorial Lecture. By F. W. CLARKE, LL.D.
18. The Mendeléeff Memorial Lecture. By Sir WILLIAM A. TILDEN, D.Sc., F.R.S.
19. The Thomsen Memorial Lecture. By Sir EDWARD THORPE, C B., D.Sc., F.R.S.
20. The Berthelot Memorial Lecture. By H. B. DIXON, C.B.E., D.Sc., F.R.S.
21. The Moissan Memorial Lecture. By Sir WILLIAM RAMSAY, K.C.B., D.Sc, F.R S.
22. The Cannizzaro Memorial Lecture. By Sir WILLIAM A. TILDEN, D.Sc., F.R.S.
23. The Bequerel Memorial Lecture. By Sir OLIVER LODGE, D.Sc., F.R.S.
24. The Van 't Hoff Memorial Lecture. By Sir JAMES WALKER, D.Sc., F.R.S.
25. The Ladenburg Memorial Lecture. By F. S. KIPPING, D.Sc., F.R.S.

Note.—These volumes are eminently suitable for school prizes.

GURNEY & JACKSON, 33 Paternoster Row, E.C.4.



THIS NEW BOOK

(List No. 169-N)

contains full particulars of various types of electrometers, and information concerning photo-electric cells. A bibliography is appended giving references to published papers on various applications of the instruments. May we send you a copy?

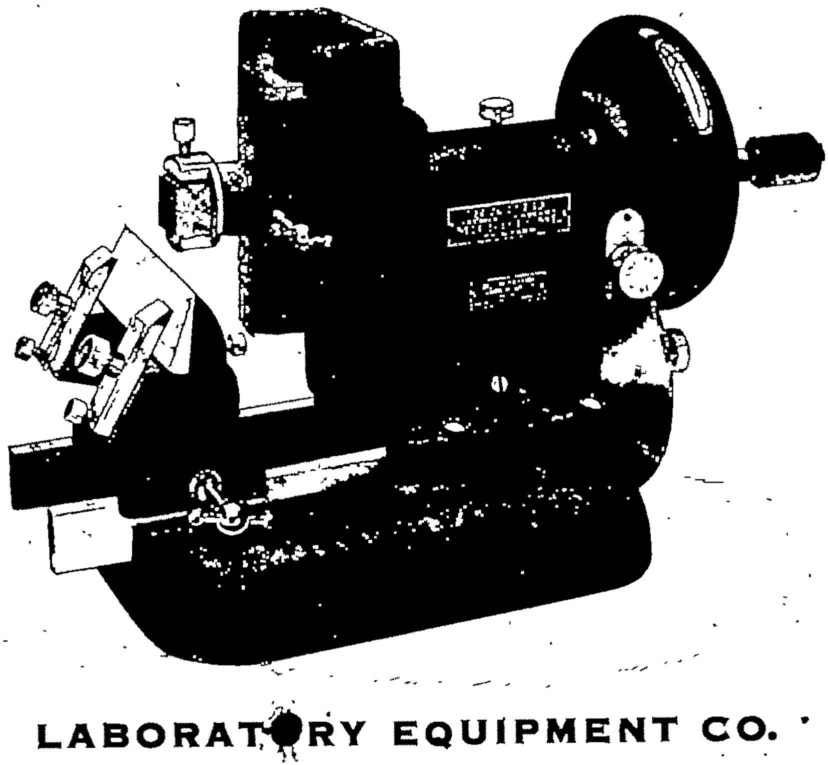
No 3. AUTOMATIC ROTARY MICROTOME



NEW AND IMPROVED MODEL

HAVING —
UNIVERSAL OBJECT CLAMP, RIGID AND PRACTICAL
KNIFE HOLDER, INSTANTLY DETACHABLE AND WITH FINE ADJUSTMENT FOR KNIFE ANGLE
MECHANISM TOTALLY ENCLOSED
PERFECTLY BALANCED ACTION
HEAVY CONSTRUCTION (WEIGHT 28 lbs)
GUARANTEED PERFORMANCE WITH EVEN CUT ON ANY MATERIAL

PRICE £17 : 17 : 6

ALSO — MICROSCOPES:— RESEARCH, BACTERIOLOGICAL, STUDENTS', DISSECTING
LAMPS — POINTOLITE, ACETYLENE
MICROTOMES — TWO OTHER TYPES
PHOTOMICROGRAPHIC APPARATUS. — TWO TYPES
EMBEDDING APPARATUS, LIGHT FILTERS, TISSUE MINCERS, METAL BENCHING AND CHAIRS, SUPPLIES

THE ASCENT OF MAN

By Means of Natural Selection

By ALFRED MACHIN

Crown 8vo. **7s. 6d.** net.

An effort at the solution of the greatest of all problems—that of the evolution of Man.

In a letter to the author **Sir ARTHUR KEITH, F.R.S.,** *says:*

"I have a very high opinion of your book on Man's evolution and it does deserve to be widely known and widely read. . . .

"Your book is not only reliable and interesting, but it puts old problems relating to man's evolution in a new way, and also in a way which the unskilled can understand."

Professor E. B. POULTON, F.R.S., *writes:*

"It is fortunate that Mr. Machin's volume should have been published at this period in the history of evolutionary thought—the period of the Tennessee proceedings and, here in England, of criticisms, which may be exemplified by the following passage printed in the *Spectator* for July 24, 1926: 'The theory of EVOLUTION BY NATURAL SELECTION, in its commonest expression—"the survival of the fittest"—adds nothing at all to our comprehension. The phrase, if it is analysed, means only "the survival of the survivors."' To this re-statement of an old objection, refuted more than fifty years ago and now revived, Mr. Machin's clearly written book supplies a convincing answer."

Professor SOLLAS, F.R.S., *writes:*

"In this interesting—and, indeed, fascinating work—we are shown that the picture of Nature 'red in tooth and claw' has been rather overdrawn.

"There is a brighter side, lit up by natural affection and even by a notable altruism.

"In insisting on this the author may be said to take the sting out of the doctrine of natural selection, and we are left to supply for ourselves, if we wish, the argument that unselfish instincts must exist, if only in germ, before they can be selected. Is it possible that we may find here a hint towards that basis for a system of ethics which many philosophers have sought after in vain?"

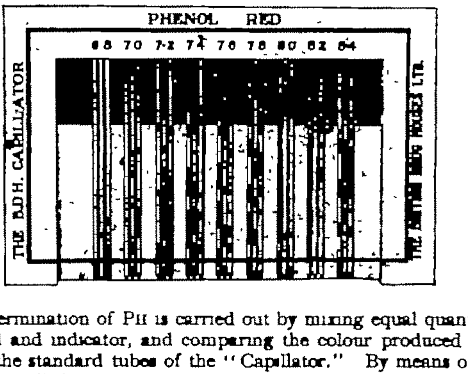
"It is a work which no student of man should omit to read"—Dr B. MALINOWSKI in *Nature*, Oct. 9, 1926.

LONGMANS, GREEN AND CO., LTD., 39 PATERNOSTER ROW, LONDON, E.C.4

B.D.H. CAPILLATOR

THE B.D.H. "Capillator" provides an improved method for the colorimetric determination of Hydrogen Ion Concentration.

The "Capillator" consists of a series of capillary tubes filled with buffer solutions containing an indicator. These tubes are mounted in threes on a white card, and form a series of coloured strips, each strip being marked with its exact PH value. Each card illustrates the complete colour change of the indicator.



A determination of PH is carried out by mixing equal quantities of liquid and indicator, and comparing the colour produced with that of the standard tubes of the "Capillator." By means of the "Capillator" determinations of PH are carried out expeditiously and accurately, and as little as one drop of the liquid will suffice for a test.

Prices and further particulars will be supplied on application.

ZENITH

NOTICE

We beg to inform our customers and suppliers that the business formerly carried on as THE ZENITH MANUFACTURING COMPANY has now been incorporated as a private company under the title of

THE ZENITH ELECTRIC COMPANY, LIMITED,

in order to provide additional capital and manufacturing facilities to cope with the increased demand for our well-known "ZENITH" electrical products.

Provision has been made for the collection by the new company of all accounts and the discharge by them of all liabilities in connection with the business, which will be continued without interruption under the same management, but the new title as above.

The directors trust that the happy relationship which has subsisted in the past will continue under the new proprietary.

THE ZENITH ELECTRIC CO. LTD.
Contractors to H.M. Admiralty, War Office, Air Ministry, Post Office, L.C.C., etc.

New and Recent Publications.

ANIMAL GENETICS

An Introduction to the Science of Animal Breeding.

By F. A. E. CREW, M D, D Sc., Ph.D., F.R.S.E., Lecturer in Genetics in the University of Edinburgh, and Director of the Animal Breeding Research Department. With one Coloured Plate, 66 Figures in the Text and a Bibliography of over 1500 References. Medium 8vo. 440 pp. 15s. net.

THE COMPARATIVE ANATOMY, HISTOLOGY, AND DEVELOPMENT OF THE PITUITARY BODY

By G. R. DE BEER, M A, B.Sc., F.L.S., Jenkinson Memorial Lecturer in Comparative and Experimental Embryology in the University of Oxford. With 11 Plates (one coloured) and 118 Figures in the Text. Medium 8vo 128 pp 12s. 6d. net.

REPRODUCTION IN THE RABBIT

By JOHN HAMMOND, M A.(Cantab.), School of Agriculture, Cambridge. With Foreword and Chapter on the Formation of the Corpus Luteum by F. H. A. MARSHALL, F R.S. With 20 full-page Illustrations Medium 8vo. 256 pp 15s. net.

STATISTICAL METHODS FOR RESEARCH WORKERS

By R. A. FISHER, M.A, Chief Statistician, Rothamsted Experiment Station. Medium 8vo. 252 pp. 15s. net.

THE PIGMENTARY EFFECTOR SYSTEM

A Review of the Physiology of Colour Response.

By LANCELOT T. HOGBEN, M.A (Cantab.), D Sc (Lond.), F.R.S (Edin.), McGill University, Montreal. Medium 8vo 164 pp. 10s 6d. net.

THE ERYTHROCYTE AND THE ACTION OF SIMPLE HÆMOLYSINS

By ERIC PONDER, Lecturer in Physiology in the University of Edinburgh. Medium 8vo. 204 pp 12s. 6d. net.

AGRICULTURE

The Science and Practice of British Farming.

By JAMES A. S. WATSON, M.C., B Sc., M.S.A.(Iowa), Professor of Agriculture, Oxford University, and JAMES A. MORE, B.Sc, N.D.A.(Hons.), N.D.D.(Hons.), Lecturer on Agriculture, University of Edinburgh; formerly Lecturer on Agriculture at the Midland Agricultural College. With 122 Illustrations. 8vo. 696 + xii pp. 15s. net.

FARM LIVE STOCK OF GREAT BRITAIN

By ROBERT WALLACE, M.A., Professor (Emeritus) of Agriculture and Rural Economy in the University of Edinburgh. Assisted by J. A. SCOTT WATSON, M.C, B Sc., Professor of Agriculture, Oxford University. Fifth Edition, Revised and Enlarged. With 442 Plates and 111 Figures in the Text. Medium 8vo 888 pp £1:10s net.

PRACTICAL BACTERIOLOGY

An Introductory Course for Students of Agriculture.

By ANDREW CUNNINGHAM, B.Sc (Agric.), Advisory Officer and Lecturer in Bacteriology, Edinburgh and East of Scotland College of Agriculture. With Illustrations. Crown 8vo. 196 pp. 7s. 6d. net.

A DICTIONARY OF SCIENTIFIC TERMS

Pronunciation, Derivation, and Definition of Terms in Biology, Botany, Zoology, Anatomy, Cytology, Embryology, Physiology.

By I. F. HENDERSON, M.A, and W. D. HENDERSON, M.A., B.Sc., Ph.D., F R.S.E. Medium 8vo. 18s. net.

FOSSIL MEN

Elements of Human Palæontology.

By MARCELLIN BOULE, Professor in the Museum National d'Histoire Naturelle, Paris; Director of L'Institut de Paléontologie Humaine. Translated from the French with an Introduction by JESSIE ELLIOT RITCHIE and JAMES RITCHIE, M.A., D.Sc, F.R.S E., Keeper of the Natural History Department, Royal Scottish Museum. Brought up-to-date with revised and enlarged Second French Edition (1923). With 250 Illustrations. Royal 8vo 532 pp. £1:16s. net.

X-Ray Apparatus

For Crystallography and Physical Research

In choosing apparatus for the application of X-rays to physical and industrial science, reliability is the factor of prime importance. Watson & Sons have a world-wide reputation for absolute reliability in connection with the manufacture of every class of X-ray apparatus, and the "Watson" housemark is accepted by discriminating experts as sufficient guarantee of superlative quality. Special attention has been given by Watson & Sons to the production of X-ray equipment for physical research work, and the Firm is prepared to give advice and to supply suitable equipment of the finest quality for this purpose.

N.100 ....

MACMILLAN'S NEW AND RECENT BOOKS.

PEOPLE OF THE VEIL. Being an Account of the Habits, Organisation, and History of the Wandering Tuareg Tribes which inhabit the mountains of Air or Asben in the Central Sahara. By FRANCIS RENNELL RODD. With 51 pages of Illustrations and 6 Maps and Plans. Super Royal 8vo. 30s. net.

Mr. Francis Rodd, son of Sir Rennell Rodd, gives in this book the record of a remarkable voyage of exploration in Africa among a people whose history and customs are very little known and of great anthropological and general interest.

IN UNKNOWN ARABIA. By MAJOR R. E. CHEESMAN, O.B.E., F.R.G.S., H.M. Consul in North-west Abyssinia. With a Foreword by SIR PERCY COX, G.C.M.G. With Illustrations and Maps. Super Royal 8vo. 25s. net.

SUNDAY TIMES.—"The illustrations are of unusual interest, and with its appendices of technical information and its maps, the book must take its place amongst the most valuable of recent exploratory works."

RITUAL AND BELIEF IN MOROCCO. By EDWARD WESTERMARCK, Ph.D., author of "The History of Human Marriage," etc. Illustrated. 2 vols. 8vo. 50s. net.

SUNDAY TIMES.—"It would be impossible to summarise this encyclopædia of fascinating information. But no one interested in the foundations of belief is likely to neglect this storehouse of evidence and scholarly elucidation."

ORIGINS OF EDUCATION AMONG PRIMITIVE PEOPLES. A Comparative Study in Racial Development. By W. D. HAMBLY, B.Sc., Anthropologist for the Wellcome Expedition to the Sudan, Assistant Curator, African Ethnology, Field Museum, Chicago. With a Preface by DR. CHARLES HOSE (of Sarawak). With 74 pages of Illustrations in half-tone and line. 8vo. 25s. net.

SUNDAY TIMES.—"It is not necessary to be an anthropologist to appreciate and enjoy Mr. Hambly's most entertaining book, for it is written as much for the layman as for the student."

THE PHYSIOLOGY OF THE CONTINUITY OF LIFE. By D. NOËL PATON, M.D., B.Sc., LL.D., F.R.S., Regius Professor of Physiology, University of Glasgow. With Illustrations. 8vo. 12s. net.

BRITISH MEDICAL JOURNAL.—"These pleasantly written lectures contain not only much information but much stimulating food for thought."

COTTON AND ITS PRODUCTION. By W. H. JOHNSON, lately Agricultural Adviser to the Australian Cotton Growing Association. With an Introduction by SIR WYNDHAM DUNSTAN, F.R.S., and a Foreword by SIR WILLIAM HIMBURY, Managing Director of the British Cotton Growing Association. With 26 Maps showing the Cotton Areas of the World. Med. 8vo. 30s. net.

INTERNATIONAL COTTON BULLETIN.—"The book is 'sound' and can be confidently recommended to those engaged in cotton growing, but seeing that spinners the world over are consuming more and more 'outside growth' of cotton, they ought to study this book as well, for it deals extensively with these kinds of cotton."

THE CULTIVATION OF CITRUS FRUITS. By HAROLD HUME. With 237 Illustrations. 8vo. 21s. net. (The Rural Science Series.)

AN OUTLINE OF PLANT GEOGRAPHY. By DOUGLAS H. CAMPBELL, Professor of Botany, Stanford University, California; author of "The Structure and Development of Mosses and Ferns." With 52 page Plates and 101 Figures in the Text. 8vo. 17s. net.

HOLISM AND EVOLUTION. By GENERAL THE RIGHT HON. J. C. SMUTS. 8vo. 18s. net.

THE DAILY TELEGRAPH.—"This presentment of his attitude towards the scheme of things is in many ways extraordinarily interesting. Even those who disagree with his conclusions will find his exposition of them very stimulating, and in the course of reading his volume they will learn a great deal probably new to them about the recent theories of science in many departments."

PROJECTIVE GEOMETRY. By CLEMENT V. DURELL, M.A., Senior Mathematical Master at Winchester College. Crown 8vo. 7s. 6d. net.

ANSWERS, HINTS AND SOLUTIONS OF THE EXERCISES IN SAME. Crown 8vo. Limp Cloth. 2s. 6d.

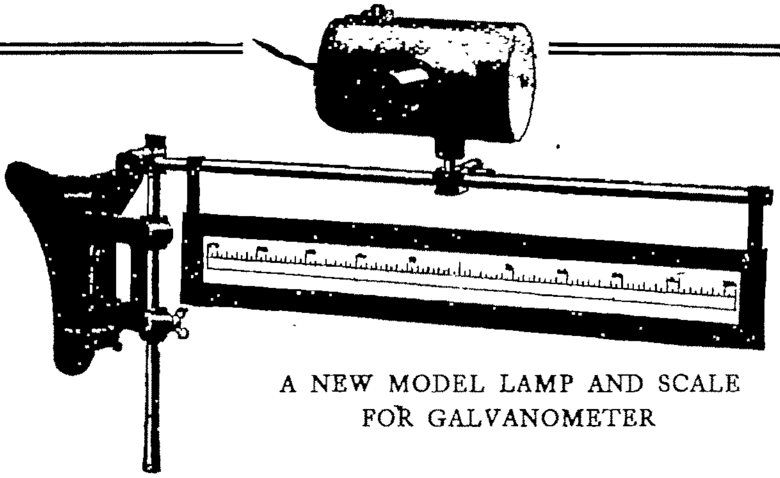
PRINTED IN GREAT BRITAIN BY R. & R. CLARK, LTD., EDINBURGH.



THE MICROID SERIES

This and other electrical instruments of new design are fully described in List No. 2M, which will be sent on application. The accuracy and sensitiveness of the new instruments are characteristic of the highest class of apparatus, and the cost is remarkably moderate.

WRITE FOR LIST 2M

A NEW MODEL LAMP AND SCALE FOR GALVANOMETER

This newly designed lamp and scale is intended to give first-class service at a comparatively low cost. Designed and used in our own test-rooms, it is provided with every useful adjustment. A clear image is obtained in bright sunlight with a 60-watt gas-filled lamp. It is made in three styles—with wall bracket, as here illustrated, clamp for shelf, and on heavy foot.

Price £4 10s.

J. H. STEWARD, Ltd.

Opticians and Scientific Instrument Makers to the British and Foreign Governments,

406 and 457 Strand, London, W.C.2.

Established 1852.

A feature of NATURE is its Supplements—the monthly one on "Recent Scientific and Technical Books" and those published occasionally on specific pieces of scientific research. In the latter class are "Electrons, Atoms and Molecules," by Prof. T. M. Lowry (May 29), and "Some New Possibilities in Solar Research," by Dr. G. E. Hale (July 3). The numbers can be sent to any address by the publishers on receipt of the published price, plus postage.

OXYGEN

And other Gases.

The British Oxygen Co. have works for the production of Oxygen, Nitrogen, Carbonic Acid, Nitrous Oxide, Hydrogen, and Argon in all chief industrial centres. The Company's Plants are capable of an aggregate output of **about four million cubic feet per day.**

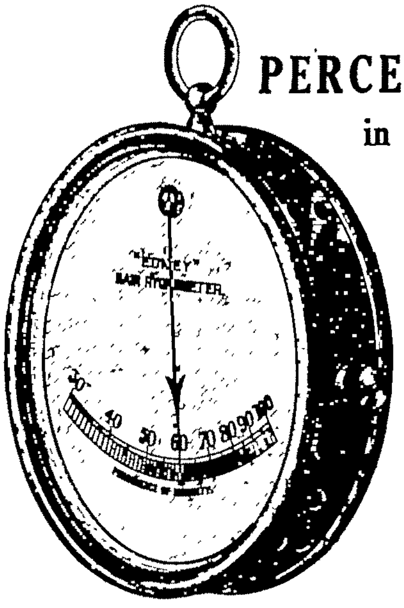
"Edney" Hair Hygrometers

showing directly the

PERCENTAGE of MOISTURE

in the room or other position where placed

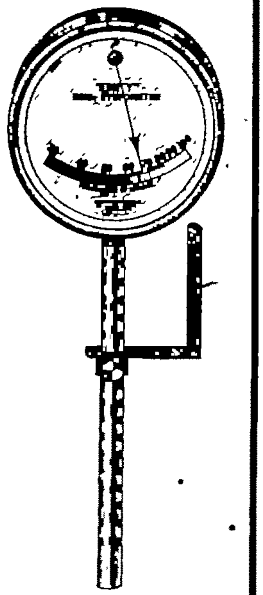


No. 1

THESE instruments are strongly made, and mounted in stout polished and lacquered brass cases, with 5-inch engraved and silvered metal dials which give a very open range, allowing the variations in humidity to be easily observed.

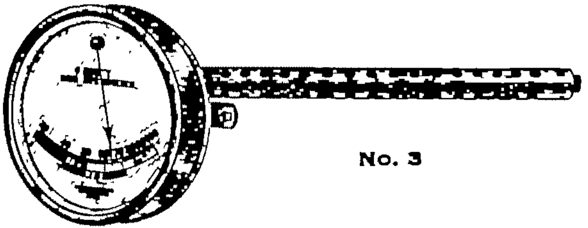
The action is by the contraction or expansion of a strand of 50 specially treated human hairs, which alters in length according to the percentage of moisture in the atmosphere.

This movement is conveyed by simple mechanism to a pulley on which the indicating hand is fixed.



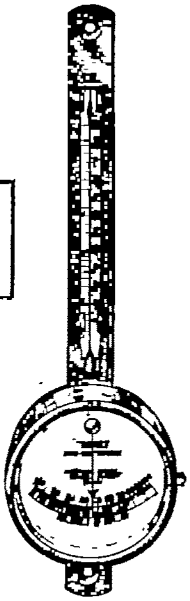
No. 2

Each instrument is tested against Standard Wet and Dry Bulb thermometers, and is guaranteed to give accurate readings.
A small adjusting screw is provided so that at any time the hand can (if required) be set to a standard.



No. 3

GUARANTEED ACCURATE



Nos. 6 and 7

PRICES

LABORATORIES
WITHOUT A SUPPLY OF GAS

should write for particulars of the Mansfield Oil-Gas plant which produces gas in a simple manner from heavy oil, such as paraffin.

The gas produced has a calorific power of about 1300 B.T.U.'s per cubic foot and gives perfect oxidising and reducing flames.

The Mansfield plant may be seen in operation in many of the principal laboratories in the British Empire which are out of the reach of a supply of town's gas.

NOW READY **Price 3s. 6d.**

A First Course in Wireless

By R. W. HUTCHINSON, M.Sc., A.M.I.E.E.

This is a scientific introduction to Wireless Telegraphy and Telephony. No previous knowledge of the subject is assumed, the theory underlying the production, propagation and detection of electromagnetic waves is treated in a simple yet scientific way, the construction and action of all essential apparatus is briefly dealt with, whilst several receiving circuits are explained and illustrated in detail. The book is specially intended for the use of technical students and wireless constructors and experimenters.

"It is one of the best works on the subject we have so far seen."—*Electricity and Electrical Engineering.*

"This is one of the most usefully comprehensive radio text-books published at a popular price we have seen."—*Popular Wireless and Wireless Review.*

MACMILLAN'S NEW AND RECENT BOOKS.

PEOPLE OF THE VEIL. Being an Account of the Habits, Organisation, and History of the Wandering Tuareg Tribes which inhabit the mountains of Air or Asben in the Central Sahara. By FRANCIS RENNELL RODD. With 51 pages of Illustrations and 6 Maps and Plans. Super Royal 8vo. 30s. net.

Mr. Francis Rodd, son of Sir Rennell Rodd, gives in this book the record of a remarkable voyage of exploration in Africa among a people whose history and customs are very little known and of great anthropological and general interest.

IN UNKNOWN ARABIA. By MAJOR R. E. CHEESMAN, O.B.E., F.R.G.S., H.M. Consul in North-west Abyssinia. With a Foreword by SIR PERCY COX, G.C.M.G. With Illustrations and Maps. Super Royal 8vo. 25s. net.

SUNDAY TIMES.—"The illustrations are of unusual interest, and with its appendices of technical information and its maps, the book must take its place amongst the most valuable of recent exploratory works."

HOLISM AND EVOLUTION. By GENERAL THE RIGHT HON. J. C. SMUTS. 8vo. 18s. net.

THE TIMES.—"With this volume General Smuts takes a high place in the small but distinguished company of British statesmen-philosophers."

A SHORT HISTORY OF MARRIAGE. By EDWARD WESTERMARCK, Ph.D. 8vo. 10s. 6d net.

RITUAL AND BELIEF IN MOROCCO. By EDWARD WESTERMARCK, Ph.D. Illustrated. 2 vols. 8vo. 50s. net.

SUNDAY TIMES.—"It would be impossible to summarise this encyclopædia of fascinating information. But no one interested in the foundations of belief is likely to neglect this storehouse of evidence and scholarly elucidation."

ORIGINS OF EDUCATION AMONG PRIMITIVE PEOPLES. A Comparative Study in Racial Development. By W. D. HAMBLY, B.Sc., Anthropologist for the Wellcome Expedition to the Sudan, Assistant Curator, African Ethnology, Field Museum, Chicago. With a Preface by DR. CHARLES HOSE (of Sarawak). With 74 pages of Illustrations in half-tone and line. 8vo. 25s. net.

SUNDAY TIMES.—"It is not necessary to be an anthropologist to appreciate and enjoy Mr. Hambly's most entertaining book, for it is written as much for the layman as for the student."

COTTON AND ITS PRODUCTION. By W. H. JOHNSON, lately Agricultural Adviser to the Australian-Cotton Growing Association. With an Introduction by SIR WYNDHAM DUNSTAN, F.R.S., and a Foreword by SIR WILLIAM HIMBURY, Managing Director of the British Cotton Growing Association. With 26 Maps showing the Cotton Areas of the World. Med. 8vo. 30s. net.

INTERNATIONAL COTTON BULLETIN.—"The book is 'sound' and can be confidently recommended to those engaged in cotton growing, but seeing that spinners the world over are consuming more and more 'outside growth' of cotton, they ought to study this book as well, for it deals extensively with these kinds of cotton."

THE CULTIVATION OF CITRUS FRUITS. By HAROLD HUME. With 237 Illustrations. 8vo. 21s. net. (The Rural Science Series.)

AN OUTLINE OF PLANT GEOGRAPHY. By DOUGLAS H. CAMPBELL, Professor of Botany, Stanford University, California; author of "The Structure and Development of Mosses and Ferns." With 52 page Plates and 101 Figures in the Text. 8vo. 17s. net.

PROJECTIVE GEOMETRY. By CLEMENT V. DURELL, M.A., Senior Mathematical Master at Winchester College. Crown 8vo. 7s. 6d.

THE MATHEMATICAL GAZETTE, in a review of the volume of which this is an abridged form, says: "The author possesses a thorough grasp of his subject, and the power of presenting it in an eminently attractive manner. . . . The book is a notable and most attractive addition to the literature of the subject."

ANSWERS, HINTS AND SOLUTIONS OF THE EXERCISES IN SAME. Crown 8vo. Limp Cloth. 2s. 6d.

MODERN GEOMETRY—THE STRAIGHT LINE AND CIRCLE. By CLEMENT V. DURELL. Crown 8vo. 5s.

MATHEMATICAL GAZETTE.—"We hope that it will become generally adopted, for it is a good book. . . . It forces the reader to think, although it is seldom hard to understand. It is also remarkably complete, nothing essential being omitted, and very little that is unessential being admitted."

PRIOR'S ULTRA-SENSITIVE SELENIUM CELLS

These Cells are the outcome of 25 years' research in selenium, and stand in a class entirely by themselves. The inertia so pronounced in all other types of selenium cells has been reduced to almost infinity, and they will remain constant for a long period.

They can be supplied in any resistance, and with a ratio up to 100 to 1 with 60-watt lamp 3″ away. We are also able to supply special Cells having a zero reading in the dark.

Scientists and research workers have described Prior's Ultra-Sensitive Selenium Cells as a wonderful scientific development, producing results hitherto considered impossible with selenium.

Recent experiments carried out with speaking film prove these Cells invaluable—tone being purer than that obtained by the use of the photo-electric cell.

All Ultra-Sensitive Selenium Cells are guaranteed for a period of six months from date of purchase.

The following represents a reading of a Cell selected at random :—

Size of active surface : 1″ × 1″.
Resistance of Cell in the dark : 350,000 ohms.
Current passed in dark at 50 volts : ·2 mA.
Distance of Cell from lamps : 12 inches.

	8 c.p. 50,000	16 c.p. 30,000	25 c.p. 25,000	32 c.p. 20,000 ohms
Current passed in mA.	1	1·5	1·8	2·25

2 mA. at 20 volts with 60-watt lamp 3″ from Cell.
The above Cell has been tested to 60 volts.

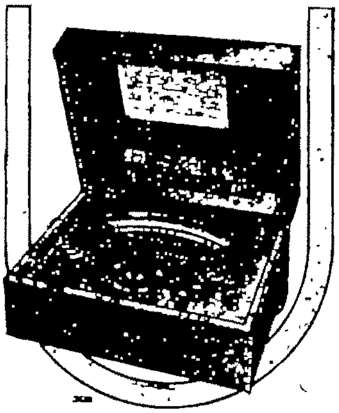
CAMBRIDGE TESTING SETS

FOR
ELECTRICAL
MEASUREMENTS

PATTERN "O"

Pressures (0·0001 to 600 volts).
Currents (1 microamp. to 150 amps.)
Resistances (10 microhms to 10 ohms).
Insulations (0·02 to 500 megohms at 500 volts).

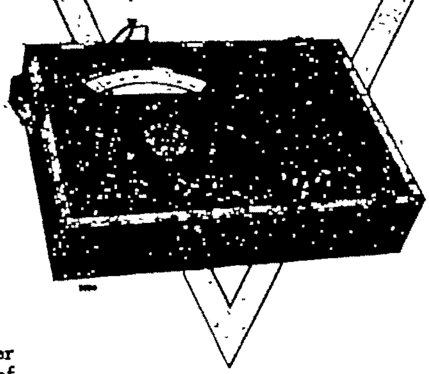


PATTERN "U"

as pattern "O," but of higher sensitivity, measures currents to 150 amps. and insulations to 1000 megohms.

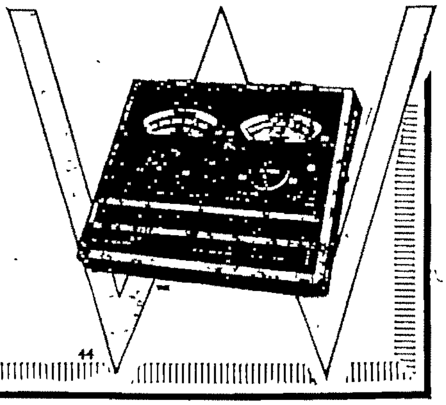
PATTERN "V"

as pattern "U," but measures resistances to 10 megohms, and capacities from 0·01 to 100 mfds.



PATTERN "W"

for stray underground electric currents up to 5000 milliamperes. Adopted by the G.P.O. for cable testing, etc.



Although these testing sets cover an exceptionally wide range of measurements, they are compact, portable, and simple to operate. They are fully described in our new 27-page List, No. 160-N. May we send you a copy?

On choosing a Loud Speaker

NO one would ever think of choosing a car without a great deal of thought and reflection. Yet how many people will buy a Loud Speaker without previously considering which type is suitable for their particular conditions? Haphazard choice of a Loud Speaker in fact has led to more dissatisfaction with radio than any other cause.

When buying a Loud Speaker consider these points:

1—TONE

First among the essentials of good reproduction is tone. Absolute freedom from distortion and a perfectly life-like rendering of every phase of the broadcast—orchestral and vocal, is necessary. It is upon this that **Brown** success has been founded.

2—VOLUME

It is essential that a Loud Speaker should be capable of giving a varied volume to meet individual needs; but whether the volume be great or small there must be no trace of distortion. There are very few Loud Speakers capable of rendering with real purity an unlimited amount of volume.

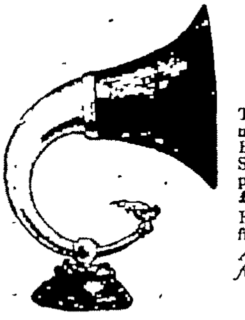
3—NAME

You may be shown Loud Speakers which *look* as good as the **Brown**, yet at much lower prices. Compare them, though, on quality of reproduction with any **Brown**—you cannot be other than impressed with the result. The name **Brown** stands for all that is best in radio reproduction—pure, unsurpassed tone combined with adequate volume.

¶

Illustrated here is the world-famous Brown "Q." It is universally acknowledged to be the height of Loud Speaker perfection.

Price £15 : 15s.



¶

There are nine models in the Brown Loud Speaker range—priced 30s. to £15·15s.

Headphones, too, from 20s. to 60s.

Ask your Dealer for a Catalogue.

McGRAW-HILL SCIENTIFIC AND TECHNICAL BOOKS

ELEMENTS OF ASTRONOMY

By EDWARD ARTHUR FATH

Professor of Astronomy in Carleton College

THIS book attempts to present the subject-matter of astronomy to those who, through disinclination or lack of time, do not wish to read an extended mathematical treatment. Very little is presented in mathematical form, but an effort has been made to develop the necessary physical concepts so that the reader will, after completing the book, be in possession of the main facts of the subject as well as have an elementary understanding of the principles and methods involved in modern astronomical investigation. Ample discussion is given to the nature of spiral nebulæ; the Bohr theory of the atom; the Einstein theory of relativity; Eddington's investigations, etc.

THE RESEARCH FOUNTAIN PEN (Patented).

Price 20s. free by post.

The ***only non-blotting*** pen the world has ever produced. Dip pens and other fountain pens required incessant care and attention in order to avoid blotting, this became a semi-conscious habit with the writer, but none the less it was a severe strain and handicap to him to have to look after his pen when his whole attention was taken up with original composition. The Research Pen requires no attention, it never blots, it may be lifted up and laid down with the certainty of being literally as cleanly as a pencil. The Research Pen is such a great change and improvement that writers really cannot form any adequate idea of its greater usefulness without trying the pen.

Another new feature is that the pen maintains a full and ***uniform*** quantity of ink on the nib This is even more important than the absence of blotting The ink on the nib of the Research Pen is like a cistern—always at the same good level and which can neither overflow nor descend below its proper height. In dip pens the ink on the nib was always lessening, in all other fountain pens the ink on the nib was continually varying in amount Hence in all former pens it rarely happened that a writer was "suited" with a nib He could not be suited when the pen wrote differently from time to time with the varying quantities of ink on the nib.

The Research Pen has proved eminently successful in getting writers suited with nibs, and we have received the most grateful of letters in consequence, we recognise and work to upwards of 100 varieties in gold nibs. The Research Pen attains a much higher standard of writing ability than former dip pen or fountain pen, and in some cases the speed of writing has been doubled

We are always glad to send a Research Pen on approbation to persons who occupy responsible positions. No statement is made regarding the pen which is not exactly true.

The Research Pen is more expensive than any other fountain pen, but the materials of the pen cost more and the workmanship is better. The penholder is made of beautifully tinted transparent bakelite There are also new parts in the pen which are not in any other pen, seeing that there are new and most valuable properties now for the first time present in any pen No trouble is experienced in filling and using the pen. It is also a most durable self-filling pen, it is the only kind of self-filling pen which is found to be durable in India and other warm countries. The Research Pen will also be found to be as cleanly as a safety pen—also a new departure.

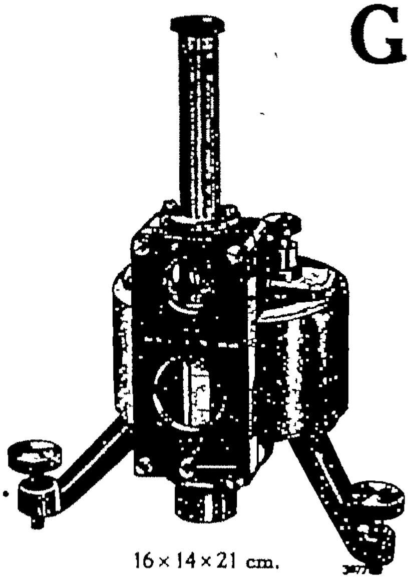
ANNOUNCEMENT.

Volume VIII. of *The Journal of General Physiology* will be a memorial to its founder, Dr. Jacques Loeb. This volume will contain papers by Dr. Loeb's pupils and his associates, together with a portrait and a sketch of his life. The volume will appear simultaneously with Volume IX. The publication of this volume began September 18, 1925.

Subscribers to the Journal, and others, may obtain the extra volume by sending their subscriptions (price $5.00) to

THE JOURNAL OF GENERAL PHYSIOLOGY,

AVENUE A AND 66TH ST., NEW YORK, N.Y.



A SIMPLE SENSITIVE GALVANOMETER

Cambridge A.M. Galvanometers can now be fitted with the Wadsworth reflecting device, whereby the normal sensitivity is doubled. For example, a galvanometer of this form, with a resistance of 25 ohms, will give a deflection of 275 millimetres per microampere at one metre scale distance, as compared with approximately half this value for the standard pattern.

16 × 14 × 21 cm.

THE PREPARATION AND ANALYSIS OF ORGANIC COMPOUNDS

By J. BERNARD COLEMAN, A.R.C.Sc., F.I.C., F.C.S., and FRANCIS ARNALL, Ph.D., M.Sc., F.I.C., Lecturer in Chemistry, Chelsea Polytechnic, London.

"This highly systematic little work places before the student a comprehensive course of practical organic chemistry . . Altogether the book is a highly useful one, and well adapted to the needs of both the beginner and the advanced student in general practical organic chemistry."—CHEMICAL TRADE JOURNAL

THE ATMOSPHERIC NITROGEN INDUSTRY

WITH SPECIAL CONSIDERATION OF THE PRODUCTION OF AMMONIA AND NITRIC ACID

By DR. BRUNO WAESER. Translated by ERNEST FYLEMAN, B.Sc., Ph.D., F.I.C.
With a FOREWORD by J. F. CROWLEY, D.Sc., B.A., M.I.E.E.

"The author has been able, by drawing on the multitudinous articles available from technical and trade literature, to present a very comprehensive account of the wide ramifications of this increasingly important industry. . . . It undoubtedly constitutes the most comprehensive account of the development of the atmospheric nitrogen industry in Germany during the War that has yet appeared, and for that one fact alone, the book merits careful attention."—CHEMICAL TRADE JOURNAL

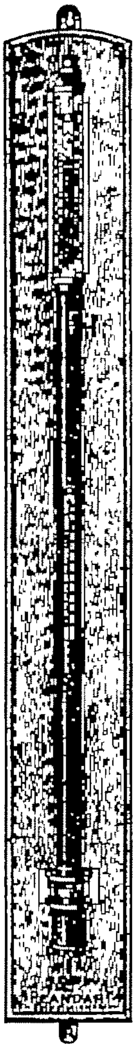
THE
IMPROVED
"PEANDAR FORTINETTE"
STANDARD BAROMETER



This Barometer has been designed to meet the requirements of **Chemical Laboratories, Gas Works, Private Observers, Colleges,** etc., for an instrument giving **exact readings** at a moderate cost. The Frame, which is made of solid drawn brass tube, is enamelled black and finished in the very best manner, and is mounted on a polished oak board, with brackets for adjustment, and opal glass reflectors behind the scales and glass cistern. Each instrument is engraved **The Improved "Peandar Fortinette" Standard Barometer.**

BORE OF TUBE - **·25-inch**

The **Scales** are engine-divided, and engraved on the brass body to ·05 inch and 1 millimetre, and read by the verniers to **·002 inch** and **·05 mm.**, and are protected by an air-tight glass cover.

The **Thermometer** has both Fahrenheit and Centigrade scales, and is protected by a metal frame.

Price, complete as illustrated,

£7 7 0

National Physical Laboratory Certificate - £2 2 0 extra. Sent **Carriage Paid,** and safe delivery guaranteed, within the British Isles.

SOLE MAKERS **PASTORELLI & RAPKIN LTD.**
46 HATTON GARDEN, LONDON, E.C.1

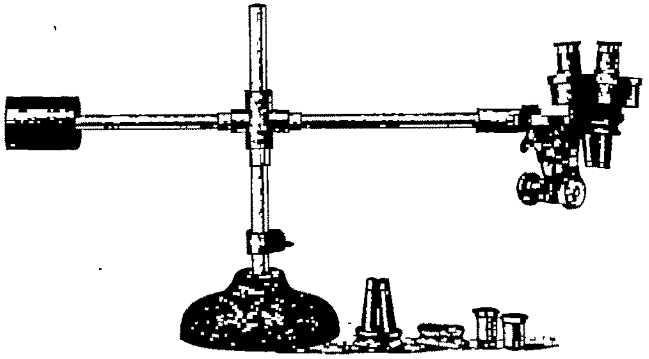
Bausch and Lomb

NEW WIDE-FIELD BINOCULAR MICROSCOPE

Designed to meet the increasing need for a high-grade binocular microscope that fulfils the following conditions:



1. **Stereoscopic Vision.**
2. **Extremely Large Field.**
3. **Long Working Distance.**
4. **High Eye Point.**
5. **Wide Range of Magnification.**

It gives the advantage of viewing the image in its true position, not inverted or reversed.

Supplied on four different stands covering every requirement, the microscope being interchangeable on each stand.

Illustrated descriptive list sent on request.

¶ **See Editorial Notice, NATURE, November 6, page 675.**

Also Microscopes for all purposes, Microtomes, Photomicrographic Apparatus, Centrifuges, Colorimeters, Hæmoglobinometers, Balopticon Projection Lanterns, etc.

Conscientiously made—for you

THE careful, conscientious workmanship—the almost loving care with which Brown workers tend the instruments they make, is almost akin to the pride with which the Craftsmen of old fashioned their work. This pride of work is distinctly reflected in the finished product—it will be obvious to you the moment you see a Brown Loud Speaker or Headphone.

Each Brown Instrument is conscientiously made; we, its sponsors, know that in it we have designed a Loud Speaker which will give the most faithful rendering of Broadcast it is possible to imagine; one that, in purity of tone and adequacy of volume, sets a standard in reproduction unequalled throughout the world. Because we want to pass this on to you, we are determined that not by the slightest deviation from the high standard of workmanship, nor by a moment's relaxing in the discernment with which only the finest quality materials are chosen, shall the astounding fidelity of Brown reproduction be prejudiced.

¶ Art and Science go hand in hand in the Brown Cabinet Loud Speaker. Beautifully finished in rich Mahogany or Oak, it will harmonise with the setting of any room, while in purity of tone and adequacy of volume it stands alone among Loud Speakers of this type. In resistances of 2000 or 4000 ohms. **£6 . 6 . 0**

RIVERS-McDOUGALL FATIGUE MACHINE

(Portable Model)

This machine provides an efficient and reliable method of studying and registering the distraction of the attention due to mental fatigue or to disturbing sensory stimuli. The test requires a maximal sustained effort of attention from the subject, and produces a continuous graphical record of the results, which lends itself to examination and analysis. The machine is useful for comparing the capacity of individuals for concentrated effort, the influence of excitement, drugs, rest, etc.

NEW
STUDENT'S MICROSCOPE STAND L O

The Microscope is one of the well-known standard Leitz series, of generous proportions, with large square object stage.
The objectives and eyepieces are of our own manufacture, entirely British, and of the highest quality, the objectives consisting of fully corrected achromatic lenses.

SPECIFICATION

L O Outfit No. 1—Microscope stand, with coarse and fine adjustments, square object stage, Abbe condenser and iris diaphragm with spiral focussing screw, and triple nosepiece. Ogilvy & Co achromatic objectives: ⅓″, 0·28 N.A., and ⅙″, 0·85 N.A. Eyepieces ×6 and ×10. Complete in cabinet £15 10 0

REPAIRS

Optical and mechanical repairs to all kinds of scientific instruments are carried out efficiently in our own workshops by thoroughly experienced mechanics

WEALTH, VIRTUAL WEALTH AND DEBT

By Professor F. SODDY. 10s. 6d.

An examination of the economic paradox that threatens the future of industrialised nations—material productivity and financial bankruptcy, glut and unemployment, superabundance and poverty, with world war as the outlet—from the standpoint of physical science.

Some Press Opinions:

"Here at long last is somebody talking about economics without seeming merely to juggle with paradoxical ideas. It is the secret of Prof. Soddy's clarity that he is a scientist."—*Granta*.

"Prof. Soddy has written a profoundly interesting book. The value of it lies in the conjunction of absolute fearlessness with a close and masterly logical analysis."—*Saturday Review*.

"A valuable contribution to economic thinking by a leading expert in a quite different branch of science."—*New Statesman*.

"A keen and successful exposure of the defects of our bank credit system together with a set of remedial proposals designed to secure a stable price level."—*New Leader*.

GEORGE ALLEN & UNWIN LTD.

New Scribner Books

OUR MOBILE EARTH

By REGINALD DALY, Head of the Department of Geology in Harvard University. With many photographs, diagrams, and maps **21s. net.**

"Our Mobile Earth" tells all that is known of the crust of the earth its origin and structure; of earthquakes; of how the continents were formed; of how the mountain chains came into being—all the successive steps of Nature in the making of the habitable world.

"Professor Daly's fascinating book."—*Morning Post*

"It should be welcome to many classes of readers: geographers, biologists and palæontologists, as well as astronomers and physicists."—*Times Literary Supplement.*

BEYOND THE MILKY WAY

By GEORGE ELLERY HALE, D.Sc., Assoc. R.A.S., Director of the Mount Wilson Observatory of the Carnegie Institution of Washington. Illustrated **7s. 6d. net.**

Dr Hale, who is well known for his pioneer work in astronomy, summarises the suppositions in regard to another universe, and outlines some of the newest discoveries both astronomical, dealing with the infinitely big, and physics—dealing with the infinitely little. He describes how the late Ernest Fox Nichols was the first to measure the heat radiation of stars, and points the way to future great developments.

By the same author.

THE NEW HEAVENS. **7s. 6d. net.**

THE DEPTHS OF THE UNIVERSE. **7s. 6d. net.**

"No one is more competent than Professor Hale to survey this great territory of which he is the leading pioneer explorer, and his account of the methods used to examine it and the rich store of new knowledge gathered from it, makes it as fascinating a scientific story as ever was told."—*Nature*

EVOLUTION AND RELIGION IN EDUCATION

By Professor HENRY FAIRFIELD OSBORN, President of the American Museum of Natural History. **7s. 6d. net.**

Professor Osborn's book sets forth the reasoned and tempered views of a great evolutionist who is also a religionist.

Other books by Professor Osborn

FROM THE GREEKS TO DARWIN. (New edition.) An outline of the development of the evolution idea. **12s. 6d. net.**

The Mouthpiece of the Ether

BEFORE you buy a Loud Speaker ask these questions · is it pure in tone?—is its volume adequate?—will it reproduce evenly and accurately music and speech alike?—will it still retain these qualities after years of use?

If the Loud Speaker you buy fails in any one of these respects, you have not made the wisest choice possible to you. For in one of the nine Brown models there is an instrument to suit your pocket, which conforms with every requirement of the perfect Loud Speaker, and which will render you the same faithful service years after, as on the day you bought it.

We do not make extravagant claims for the Brown—it is not necessary. An instrument which has risen in a few years from a small "local" sale to world-wide fame; which has found its way into the homes of people of every nationality; and whose name has come to be universally regarded as a veritable synonym for perfect Radio reproduction—a Loud Speaker with such a record of achievement behind it surely needs no further recommendation.

¶ In the Brown H.Q. model are to be found a beauty of outline and perfect balance rarely seen in a Loud Speaker, with tonal purity and astonishing volume such as the most discerning could not wish to better. Standing twenty inches in height and in resistances of 2000 or 4000 ohms. **£6.0.0**

LONDON, W.1.

For Accurate Control

The "Coolidge" X-Ray Tube

The "Coolidge" tube is unequalled for physical and industrial X-ray work because it allows of an accuracy of control impossible with other types of tube. Both the quantity and penetrating power of X-rays delivered are under the complete control of the operator when the "Coolidge" tube is used, the quantity varying in direct proportion to the temperature of the cathode filament, and the penetrating power in direct proportion to the potential applied to the tube. You know exactly what you are doing when you use a "Coolidge" tube, and you can repeat accurately a given set of conditions at any time. If you value scientific accuracy, pin your faith to the "Coolidge" tube.

Send for full particulars and prices.

MACMILLAN'S NEW AND RECENT BOOKS.

REALITY: A NEW CORRELATION OF SCIENCE AND RELIGION. By BURNETT HILLMAN STREETER, Canon of Hereford. 8s. 6d. net.

This book is a plain and popular statement of a position which the author has reached after many years of reflection and much discussion with persons of different points of view.

NATURAL MAN: A RECORD FROM BORNEO. By CHARLES HOSE, Hon. Sc.D., formerly Divisional Resident, and member of the Supreme Council of Sarawak. With a Preface by PROF. G. ELLIOT SMITH, F.R.S. With Illustrations and Map. Super Royal 8vo. 30s. net.

PEOPLE OF THE VEIL. Being an Account of the Habits, Organisation, and History of the Wandering Tuareg Tribes which inhabit the mountains of Air or Asben in the Central Sahara. By FRANCIS RENNELL RODD. With 51 pages of Illustrations and 6 Maps and Plans. Super Royal 8vo. 30s. net.

THE WESTMINSTER GAZETTE.—"Mr. Francis Rennell Rodd's record of travel and adventure, and his character-drawing of the many strange people with whom he came in contact, make his work one of serious geographical and ethnographical value."

IN UNKNOWN ARABIA. By MAJOR R. E. CHEESMAN, O.B.E., F.R.G.S., H.M. Consul in North-west Abyssinia. With a Foreword by SIR PERCY COX, G.C.M.G. With Illustrations and Maps. Super Royal 8vo. 25s. net.

THE TIMES LITERARY SUPPLEMENT.—"The interest of this book is so various and it is so eminently readable that those who feel no particular concern with Arabia will find it as attractive as those who do."

A SHORT HISTORY OF MARRIAGE. By EDWARD WESTERMARCK, Ph.D., Author of "Ritual and Belief in Morocco," etc. 8vo. 10s. 6d. net.

ORIGINS OF EDUCATION AMONG PRIMITIVE PEOPLES. A Comparative Study in Racial Development. By W. D. HAMBLY, B.Sc., Anthropologist for the Wellcome Expedition to the Sudan, Assistant Curator, African Ethnology, Field Museum, Chicago. With a Preface by DR. CHARLES HOSE (of Sarawak). With Illustrations. 8vo. 25s. net.

SUNDAY TIMES.—"It is not necessary to be an anthropologist to appreciate and enjoy Mr. Hambly's most entertaining book, for it is written as much for the layman as for the student."

HOLISM AND EVOLUTION. By GENERAL THE RIGHT HON. J. C. SMUTS. 8vo. 18s. net.

THE OBSERVER.—"An important contribution to the new world-outlook that is preparing."

PROJECTIVE GEOMETRY. By CLEMENT V. DURELL, M.A., Senior Mathematical Master at Winchester College. Crown 8vo. 7s. 6d.

THE MATHEMATICAL GAZETTE, in a review of the volume of which this is an abridged form, says: "The author possesses a thorough grasp of his subject, and the power of presenting it in an eminently attractive manner. . . . The book is a notable and most attractive addition to the literature of the subject.'

ANSWERS, HINTS AND SOLUTIONS OF THE EXERCISES IN SAME. Crown 8vo. Limp Cloth. 2s. 6d.

HIGHER MATHEMATICS FOR STUDENTS OF ENGINEERING AND SCIENCE. By FREDERICK G. W. BROWN, M.Sc.(London), F.C.P., Senior Mathematical Master, West Ham Secondary School. Crown 8vo. 10s.

WORLD POWER.—"The author is quite right in the claim made in the preface 'that the book should be of service to all students reading mathematics for a degree, whether in arts, science, or engineering.' The book is an excellent one and should find a wide field of usefulness."

AN ATLAS OF HUMAN ANATOMY FOR STUDENTS AND PHYSICIANS. By CARL TOLDT, M.D., assisted by PROFESSOR A. D. ROSA, M.D. Adapted to English and American and International Terminology by M. EDEN PAUL, M.D.Brux., M.R.C.S., L.R.C.P. Revised Edition. With 1505 Illustrations. 2 vols. Demy 4to. 42s net.

CURRICULUM PROBLEMS. By THOMAS H. BRIGGS, Teachers College, Columbia University. Crown 8vo. 4s. 6d. net.

**** Send for Macmillan's Illustrated Christmas Catalogue, post free on application.***

SUNDAY TIMES.—"It is not necessary to be an anthropologist to appreciate and enjoy Mr. Hambly's most entertaining book, for it is written as much for the layman as for the student."

PROJECTIVE GEOMETRY. By CLEMENT V. DURELL, M.A., Senior Mathematical Master at Winchester College. Crown 8vo. 7s. 6d.

THE MATHEMATICAL GAZETTE, in a review of the volume of which this is an abridged form, says: "The author possesses a thorough grasp of his subject, and the power of presenting it in an eminently attractive manner. . . . The book is a notable and most attractive addition to the literature of the subject."

ANSWERS, HINTS AND SOLUTIONS OF THE EXERCISES IN SAME. Crown 8vo. Limp Cloth. 2s. 6d.

HIGHER MATHEMATICS FOR STUDENTS OF ENGINEERING AND SCIENCE. By FREDERICK G. W. BROWN, M.Sc.(London), F.C.P., Senior Mathematical Master, West Ham Secondary School. Crown 8vo. 10s.

WORLD POWER.—"The author is quite right in the claim made in the preface 'that the book should be of service to all students reading mathematics for a degree, whether in arts, science, or engineering.' The book is an excellent one and should find a wide field of usefulness."

AN ATLAS OF HUMAN ANATOMY FOR STUDENTS AND PHYSICIANS. By CARL TOLDT, M.D., assisted by PROFESSOR A. D. ROSA, M.D. Adapted to English and American and International Terminology by M. EDEN PAUL, M.D.Brux., M.R.C.S., L.R.C.P. Revised Edition. With 1505 Illustrations. 2 vols. Demy 4to. 42s. net.

PRINCIPLES OF GENERAL CHEMISTRY. By STUART R. BRINKLEY, Assistant Professor of Chemistry, Yale University. Illustrated. 8vo. 15s. net.

LABORATORY MANUAL. Arranged to accompany "Principles of General Chemistry." By STUART R. BRINKLEY and ERWIN B. KELSEY, Assistant Professors of Chemistry, Yale University. Illustrated. 8vo. 6s. 6d. net.

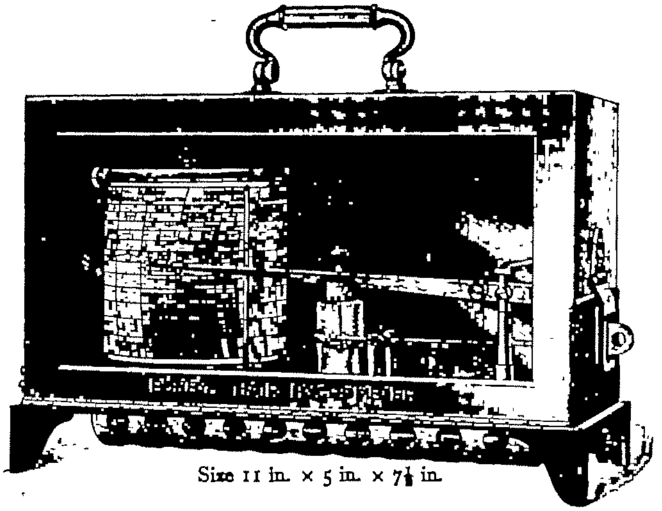
MACMILLAN & CO., LTD., LONDON, W.C.2.

"EDNEY" HAIR HYGROGRAPHS

of guaranteed accuracy



Size 11 in. × 5 in. × 7½ in.

THE "EDNEY" HAIR HYGROGRAPH

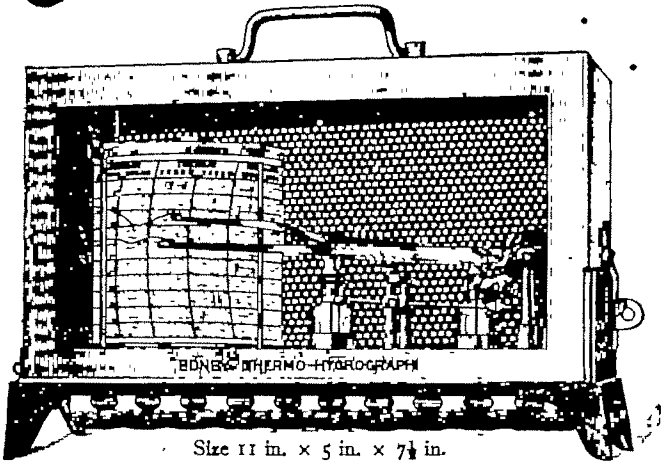
records directly the **percentage of humidity** in the atmosphere of the room or place being tested. Actuated by a string of human hair, the movement is transmitted through levers to the pen, which records on the chart the exact percentage of humidity. The chart is ranged 0-100 per cent. The Instrument is strongly mounted on cast-iron base with hinged copper cover.

Price complete, with charts for one year and bottle of ink **£8 0 0**

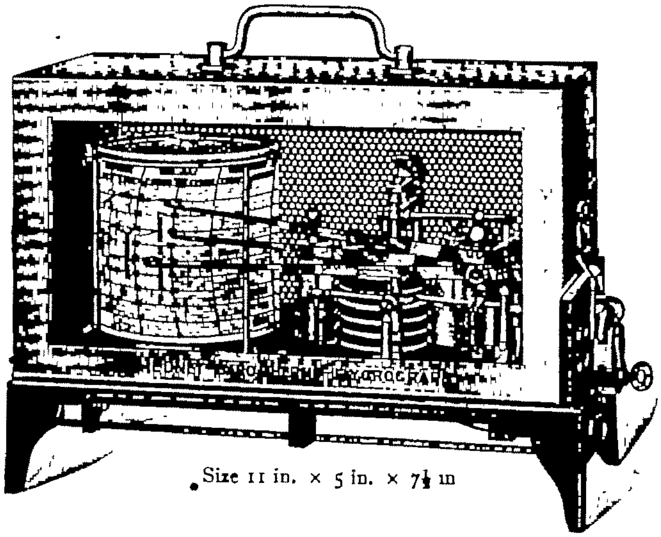
THE "EDNEY" THERMO-HYGROGRAPH

records on the same chart by different coloured inks the **temperature and humidity** of the atmosphere. The chart is ranged 0-100 Faht. and 0-100 per cent. The Instrument is strongly mounted on cast-iron base with hinged copper cover.

Price complete, with charts for one year and red and blue inks . . . **£12 12 0**



Size 11 in. × 5 in. × 7½ in.



Size 11 in. × 5 in. × 7½ in.

THE "EDNEY" BARO-THERMO-HYGROGRAPH

records on the same chart by three different coloured inks the **pressure, temperature, and humidity** of the atmosphere. The chart is ranged 28·5-31 ins., 0-100 Faht., and 0-100 per cent. The Instrument is strongly mounted on cast-iron base with hinged copper cover

Price complete, with charts for one year, and red, blue, and green inks . . **£16 16 0**

SOLE MAKERS **PASTORELLI & RAPKIN LTD.** (ESTAB. 1750), **46 Hatton Garden, LONDON, E.C.1**

Telephone: Holborn 1981] ***Any instrument sent on approval if desired.*** [*Telegrams:* Rapkin, London

Carriage paid and safe delivery of all our instruments guaranteed within the British Isles.

BLACKIE'S LIST

TWO IMPORTANT NEW BOOKS

Just Published

SPACE AND TIME

By ÉMILE BOREL

Honorary Director of L'École Normale Supérieure; Professor of Mathematical Physics in the Faculty of Sciences of Paris; Member of the Institute

Large Crown 8vo. Price **7s. 6d.** net

A semi-popular account of the Theory of Relativity by one of the most distinguished of living French mathematicians Beginning with the principles of space and time measurement, it leads up to Einstein's epoch making idea Professor Borel has specially added for the English edition an extended discussion of recent theoretical and experimental researches.

Ready shortly

THE ABSOLUTE DIFFERENTIAL CALCULUS

By TULLIO LEVI-CIVITA

Professor of Rational Mechanics in the University of Rome Fellow of the R. Accademia Nazionale dei Lincei

Demy 8vo. Price **21s.** net.

A concise and lucid account of the Calculus of Tensors by the eminent Italian mathematician who, with Ricci, discovered the method, and to whom many of its most powerful developments are solely due.

The book appeared in Italian in 1925, but the English translation has been specially revised by the author, who has contributed for the English edition two entirely new chapters on the physical applications of the method The translation has been made by Miss M. Long, equal to Fourth Wrangler in the Mathematical Tripos, Scholar of Girton College, and formerly Assistant Lecturer, Bedford College for Women.

THE CALCULUS OF OBSERVATIONS:

A Treatise on Numerical Mathematics. By E T. WHITTAKER, Sc.D., F.R.S., Professor of Mathematics in the University of Edinburgh, and G. ROBINSON, M.A., B.Sc., Lecturer in Mathematics in the University of Edinburgh. Large Demy 8vo. xvi+392 pages. **Second Edition (Third Impression). 18s. net.**

This book covers completely the course of study prescribed for London University B.Sc. Honours in Mathematics. Part II.; Pure Mathematics, Section 5.

PLANE GEOMETRY. An Account of the more Elementary Properties of the Conic Sections, treated by the Methods of Pure and Co-ordinate Geometry. By L. B. BENNY, M.A.(Cantab.), B.A.(Lond.), F.R.A.S., sometime Mathematical Scholar of Christ's College, Cambridge; Principal of Leigh Technical School, Lancs. Large Crown 8vo. **10s. 6d. net.**

This book covers one of the alternative courses in Geometry for the Pass B.Sc. Examination of the University of London in Pure Mathematics.

APPLIED CALCULUS. By F. F. P. BISACRE, O.B.E., M.A., B.Sc., A.M.Inst.C.E. Large Crown 8vo. **10s. 6d. net.**

This book has been specially written for science and engineering students who desire to acquire a working knowledge of the calculus, but whose preliminary mathematical equipment is slight.

A GENERAL TEXT-BOOK OF ELEMENTARY ALGEBRA. By E. H. CHAPMAN, M.A. (Cantab.), D.Sc.(Lond.), Headmaster, Ernest Bailey Secondary School, Matlock. With or without Answers. **7s. 6d. net.**

A complete course in Algebra for the Final B.Sc. Examination of London University.

Write for New Catalogue of Advanced Scientific and Technical Books.

BLACKIE AND SON, LIMITED
50 Old Bailey, London, E.C.4.

JOHN MURRAY

By VISCOUNT HALDANE

Human Experience: A Study of its Structure. "Full of that quiet scholarship, sound reasoning, and swift mastery of a problem characteristic of the author." —*Daily Telegraph.* **6s.** net.

The Reign of Relativity. As a result of conversations with Professor Einstein, Lord Haldane has added fresh paragraphs to this new edition. Fourth Edition. **21s.** net.

The Philosophy of Humanism and of other Subjects. An admirable sequel to "The Reign of Relativity."—*Manchester Guardian.* **12s.** net.

By Prof. FREDERICK SODDY, M.A., F.R.S.

The Interpretation of Radium and the Structure of the Atom. "Admirably conceived."—*Spectator.* Fourth Edition. Revised and Enlarged. With Illustrations. **15s.** net.

Science and Life. Aberdeen Addresses. "We are the Professor's debtor for a most suggestive book."—*Morning Post* Third Impression. **10s. 6d.** net.

Cloud Studies. By ARTHUR W. CLAYDEN. Second Edition. Re-arranged and Enlarged. 64 Illustrations. **15s.** net

Heredity. By J. A. THOMSON, M.A., LL.D. New and Fifth Edition. Thoroughly Revised. **21s.** net.

Variation, Heredity and Evolution, Recent Progress in the Study of. By R. H. LOCK, M.A., Sc.D. Fifth Edition. Revised by LEONARD DONCASTER, Sc.D., F.R.S. With Portraits and Diagrams. **9s.** net.

Mechanism, Life and Personality. An Examination of the Mechanistic Theory of Life and Mind. By J. S. HALDANE, M.D., LL.D., F.R.S., University of Oxford Second Edition. **6s.** net.

Practical Zoology, A Junior Course of. By the late Prof. A. MILNES MARSHALL, M.D., D.Sc., F.R.S., and the late HERBERT HURST, M.D. Ninth Edition Revised by Prof. F. W. GAMBLE, D.Sc., F.R.S., University of Birmingham. **12s.** net.

The Realm of Nature. An Outline of Physiography. By H. R. MILL, D.Sc., LL.D. Third Edition (Tenth Impression). Revised and entirely Reset. **7s. 6d.** net.

Microscopy. The Construction, Theory and Use of the Microscope. By EDMUND J. SPITTA, F.R.A.S., F.R.M.S. Diagrams and Illustrations. Third Enlarged Edition. **25s.** net.

Physical Science, The Recent Development of. By WILLIAM C. DAMPIER WHETHAM, M.A., F.R.S. Fifth Edition Entirely Revised and greatly Enlarged. **9s.** net

Splendours of the Sky. By ISABEL M. LEWIS. "Her object has certainly been pleasantly fulfilled, without the slightest loss of accuracy." —*Morning Post.* Illustrated. **9s.** net.

John Murray, Albemarle St., London, W.1

FROM CONSTABLE'S LIST

NOMOGENESIS or EVOLUTION DETERMINED BY LAW. L. S. BERG, D.Sc. With an Introduction by D'ARCY WENTWORTH THOMPSON. Demy 8vo. Illustrated. 28s. net.

FROM A REVIEW IN NATURE.

"This volume represents the mature thought of an accomplished ichthyologist and traveller who speaks from the point of view of a naturalist and field observer and marshals, in the first nine chapters, all the difficulties that have arisen through field observation in the original concept of Darwinism. . . . A thoughtful and, in large part, original contribution to the newer modern aspect of the evolution theory."—*Oct.* 30, 1926.

WIRELESS PICTURES AND TELEVISION. An Account of the Apparatus used and Experiments carried out for the Transmission of Photographs by Telegraphy and of Television, which will appeal alike to the highly technical and the lay reader. By T. THORNE BAKER, F.C.S., F.R.P.S. Crown 8vo. Illustrated. 6s. 6d. net.

FIELD ASTRONOMY. For Engineers and Surveyors. By DAVID CLARK, M.A., B.Sc., M.Inst.C.E. Crown 8vo. Illustrated. A manual for University and private students of surveying and geodesy. 10s. 6d. net.

PRINCIPLES OF HUMAN GEOGRAPHY. By P. VIDAL DE LA BLACHE. Edited by EMMANUEL DE MARTONNE. Demy 8vo. Illustrated. 18s. net.

PHOTOMETRY. JOHN W. T. WALSH, M.A., M.Sc., A.M.I.E.E., F.Inst.P. Royal 8vo. Illustrated. 40s. net.

SYSTEMATIC ORGANIC CHEMISTRY. A complete laboratory guide to the preparations and estimations of Organic Chemistry. W. M. CUMMING, D.Sc., F.I.C.; I. V. HOPPER, Ph.D., B.Sc., A.R.C.Sc.I., F.I.C.; and T. S. WHEELER, Ph.D., B.Sc., F.R.C.Sc.I., F.I.C. Demy 8vo. Illustrated. 25s. net.

THE STATES OF AGGREGATION: The Changes in the State of Matter in their Dependence upon Pressure and Temperature. GUSTAV TAMMANN, Director of the Institute of Physical Chemistry at the University of Göttingen. Authorised translation from the 2nd German Edition by R. F. MEHL, Ph.D. Demy 8vo. 308 pages. Illustrated. 24s. net.

INTRODUCTION TO THEORETICAL PHYSICS. ARTHUR HAAS, Ph.D. Translated by [illegible] VERSCHOYLE. 2 volumes. Demy 8vo. Illustrated. Vol. I., 21s. net.
Vol. II., 21s. net

10 & 12 ORANGE ST., LONDON, W.C.2

"In years to come the publication of this monumental work will rank as one of the milestones in British applied science."—*Nature.*

CONTENTS

Vol. I. Mechanics—Engineering—Heat.
" II. Electricity.
" III. Meteorology, Metrology, and Measuring Apparatus.
" IV. Light—Sound—Radiology.
" V. Aeronautics—Metallurgy—General Index.

THE COMPLETE WORK
IN 5 VOLUMES
Delivered
at once
FOR A FIRST PAYMENT OF
21/-
AND 14 FURTHER MONTHLY PAYMENTS OF 21/- THUS COMPLETING THE SUBSCRIPTION
PRICE - £15 15 0

Authoritative Reviews:

"This encyclopædic work differs from many that have preceded it in that it is produced by those who have worked strenuously and successfully to promote knowledge. Originality of treatment and masterly handling are everywhere exhibited."—*Engineering.* (Vol 1)

"A book which every electrical engineer ought to possess. . . . A mine of information in a field which, at present, is not adequately covered by any one work."—*The Electrician.* (Vol. 2.)

"As a summary of our present knowledge of certain aspects of meteorology, the work is of great value. It will perhaps be regarded in future as a milestone showing the stage reached by the science at the end of the great war."—*The Meteorological Magazine.* (Vol. 3.)
